

D

4. The sump pump in the pit, pumps the dirty water through a hydroclone which separates the solids out of the water into a decanter sludge box.
5. Sludge in the main pit and decanter sludge box is periodically removed and disposed as a hazardous waste.
6. Dirty wash water is periodically removed and disposed as hazardous waste and replaced with fresh water.

#### Leachate Disposal System

Engineering plans for the leachate disposal system are provided in Attachment 14.

The system includes:

1. Double containment from disposal cell to sanitary sewer
2. Double containment monitoring capability
3. Flow metering
4. Clean out capability
5. Underground storage capability

#### Electrical Distribution System

Engineering design drawings for electrical distribution at the site are in Attachment 14. Power is distributed from the wheel wash building to various locations on site to operate the air monitoring stations, discharge pumps, flow meters, etc.

#### System to Control Haul Road Run-Off

Operational procedures to minimize the likelihood of waste getting into the surface drains are utilized so as not to impact surface water quality. Such procedures include cleaning off the unloading vehicles prior to leaving the disposal cell, maintaining adequate daily cover in the unloading area so that vehicles are not exposed to the facility waste and maintaining haul roads by scraping up and disposing of any track out material.

### System to Control Haul Road Run-Off (cont'd).

In addition to these procedures, a filter barrier will be staked along the road edge to prevent any potential track out material from uncontrollably entering the edgedrains in satisfaction of R299.9604. Material accumulated against the barrier will be removed on a regular basis for disposal. Run off from the haul roads over the past five years of facility operation has not impacted surface water quality according to the quarterly monitoring program.

### Recordkeeping

Testing data and records that are required by the construction permit or operating license shall be kept in the facility operating notebook.

The waiver provision was developed specifically for facility site locations such as the Allen Park Clay Mine based on the following discussion published in the Federal Register.

Fourth, the owner or operator of a regulated unit may be excluded from Subpart F if the Regional Administrator finds that there is no potential for hazardous constituents to migrate from the regulated unit to the uppermost aquifer during the active life of the unit (including the closure period) and the post-closure care period specified under § 264.117. This exclusion is designed for units located in hydrogeologic settings that prevent leachate migration to ground water for very long periods. In such a setting, hazardous waste leachate would simply not be able to

reach ground water during the active life of the unit and the post-closure care period. Where there is a high degree of confidence that such a hydrogeologic setting is present, EPA decided that it would be of little value to require the permittee to implement a detection monitoring program. (Such a program would simply not detect contamination during the active life of the regulated unit plus the post-closure care period.)

Moreover, EPA believes it may be productive to exclude such locations from ground-water monitoring. Such locations are relatively desirable for waste disposal because soils which provide long delays in the arrival of leachate in ground water may also have characteristics that attenuate hazardous constituents. Excluding ground-water monitoring requirements at such locations could encourage the use of such environmentally desirable locations.

Ford Motor Company

Allen Park Clay Mine Landfill

E.P.A. I.D. No. MID 980568711

Demonstration for Exemption of Subpart F Requirements  
Under 40 CFR 264.90 (b) (4) and 40 CFR 265.90 (c)

Demonstration is hereby made to waive certain groundwater monitoring requirements as provided for under 40 CFR 264.90 (b) (4) and 40 CFR 265.90 (c) of the RCRA rules, based on the favorable site geology to the aforementioned rules. Specifically, the requested exemption includes all sampling of the artesian aquifer immediately below the insitu saturated clay liner.

Site Description

Depositional Environment:

The site hydrology is governed by the last glacial period in which the Huron-Erie ice lobe occupied southeast Michigan as shown on Exhibit A. When the ice lobe retreated, a proglacial lake (Lake Maumee) formed, as shown on Exhibits B and C. The site vicinity is located at least 16 miles from the shores of this lake. The clay sediments deposited in the site vicinity reflect this low energy depositional environment. The lacustrine clay is generally 80-120 feet in thickness and has become an effective aquiclude since the recession of the lake. The recharge area for the underlying aquifer is the moraine and outwash complex to the northwest and the underlying Devonian carbonate formations. There are no groundwater withdrawal wells within a three mile radius of the facility.

Artesian Aquifer:

The confined aquifer is located approximately 70 feet below the existing grade at the Allen Park site and varies in thickness from one to six feet. It exerts an upward hydrostatic pressure on the clay aquiclude equivalent to 80 feet of head. This hydraulic gradient in the upward direction is a counteracting force against those of leachate migration (drag coupling effect and chemico-osmotic diffusion). Under these conditions, there is no potential for migration of liquid from the regulated unit to the uppermost aquifer during the active life of the regulated unit and the post-closure care period. Refer to Exhibit D for a full discussion on leachate migration at the facility.

Subsurface Soil Conditions:

The uniformity of the clay sediments in the Detroit area (Erie-St. Clair Plain) has been documented by the numerous soils exploration and foundation engineering studies required for all of the building and construction projects in the vicinity.

To be site specific, the following documentation has been established:

- 1) Clay mining operations, excavating clay for the manufacture of cement, have encountered more than 45 feet of uniform material over the entire site.
- 2) Seismic work on the cell bottom indicates that the bedrock is between 57 and 70 feet below the cell bottom with uniform material to that depth.

Refer to Exhibit E.

- 3) Soil samples taken from the five most recent borings indicate the clays are saturated to the surface from the artesian aquifer. Refer to Exhibit F.
- 4) Soil tests performed (grain size analysis, atterberg limits and permeability) on the clay provided more than adequate uniformity. Refer to Exhibit G.
- 5) The 12 deep borings indicate uniform soil conditions. Refer to Exhibit H.
- 6) The deep monitor wells into the artesian aquifer provide piezometric surface elevations that are consistent with the regional data which conclude that ground surface is below the piezometric surface. Refer to Exhibit H.
- 7) Additional studies, maps, and tests relating to subsurface conditions at the site indicate that subsurface clay is in excess of 25 feet thick with a permeability coefficient which is no greater than  $6.0 \times 10^{-8}$  cm/sec. In addition, the underlying artesian aquifer exerts hydrostatic pressure in an upward direction which precludes the possibility of leakage from the cell into the liner during the active life of the disposal facility. Refer to Exhibit H.
- 8) Water balance of precipitation, evapotranspiration, runoff and infiltration. Refer to Exhibit I.
- 9) Additional geological information is provided by W. H. Sherzer, "Geological Report on Wayne County", Publication 17, Geological Series 9, 1913.

Summary:

Under the conditions stated in this demonstration, there is no potential for migration of liquid from the regulated unit to the uppermost aquifer during the active life of the regulated unit and the post-closure care period. The monitoring of water quality in the artesian aquifer cannot possibly detect leachate migration from the overlying disposal site. Accordingly, it is therefore believed that the Allen Park Clay Mine Landfill qualifies for the groundwater monitoring waiver set forth under the applicable regulations.

Ann Arbor, Michigan

July 1983

## SUMMARY

The possibility of leachate migration downward from the Allen Park Clay Mine/Landfill and contamination of an aquifer beneath were evaluated.

Analyses show that density differences between the leachate and groundwater will not cause a downward migration nor will they lead to a diffusion efflux from the site. A thick, uniform layer of silty clay beneath the site coupled with an upward hydraulic gradient effectively precludes the latter.

Comparison with results of salt water intrusion studies across clay aquitards having similar properties as the clay beneath the Allen Park site show that the solute (salt) will take at least 800 years to migrate across a clay barrier 30 feet thick under chemico-osmotic diffusion alone. A counter (or upward) hydraulic gradient will lengthen this breakthrough time even further.

There are insufficient amounts of organic compounds in the waste to affect the permeability of the clay. The probability of accelerated leachate migration through the underlying clay is not supported by the composition of the wastes and the nature of the clay nor by the findings of leachate permeability studies reported in the technical literature.

Under these circumstances any observed increases in contaminant levels of monitor wells in the aquifer underlying the site could more reasonably come from sources laterally upgradient from the site rather than the clay mine/landfill above the site.

## CONTAINMENT INTEGRITY OF ALLEN PARK CLAY MINE/LANDFILL

### I. INTRODUCTION

The Ford Motor Company who operate the Allen Park Clay Mine/Landfill have recently petitioned to discontinue ground water monitoring of an aquifer located approximately 70 feet below existing grade at the site. The landfill is underlain by dense, lacustrine clay which behaves as an aquiclude or aquitard. At least 25 feet or more of residual clay thickness separates the bottom of the landfill from the underlying aquifer. The aquifer is under artesian pressure and exerts an upward hydrostatic pressure on the base of the clay aquitard equivalent to 80 feet of head. A general cross section or profile illustrating these soil and hydrologic conditions at the site is shown in Figure 1.

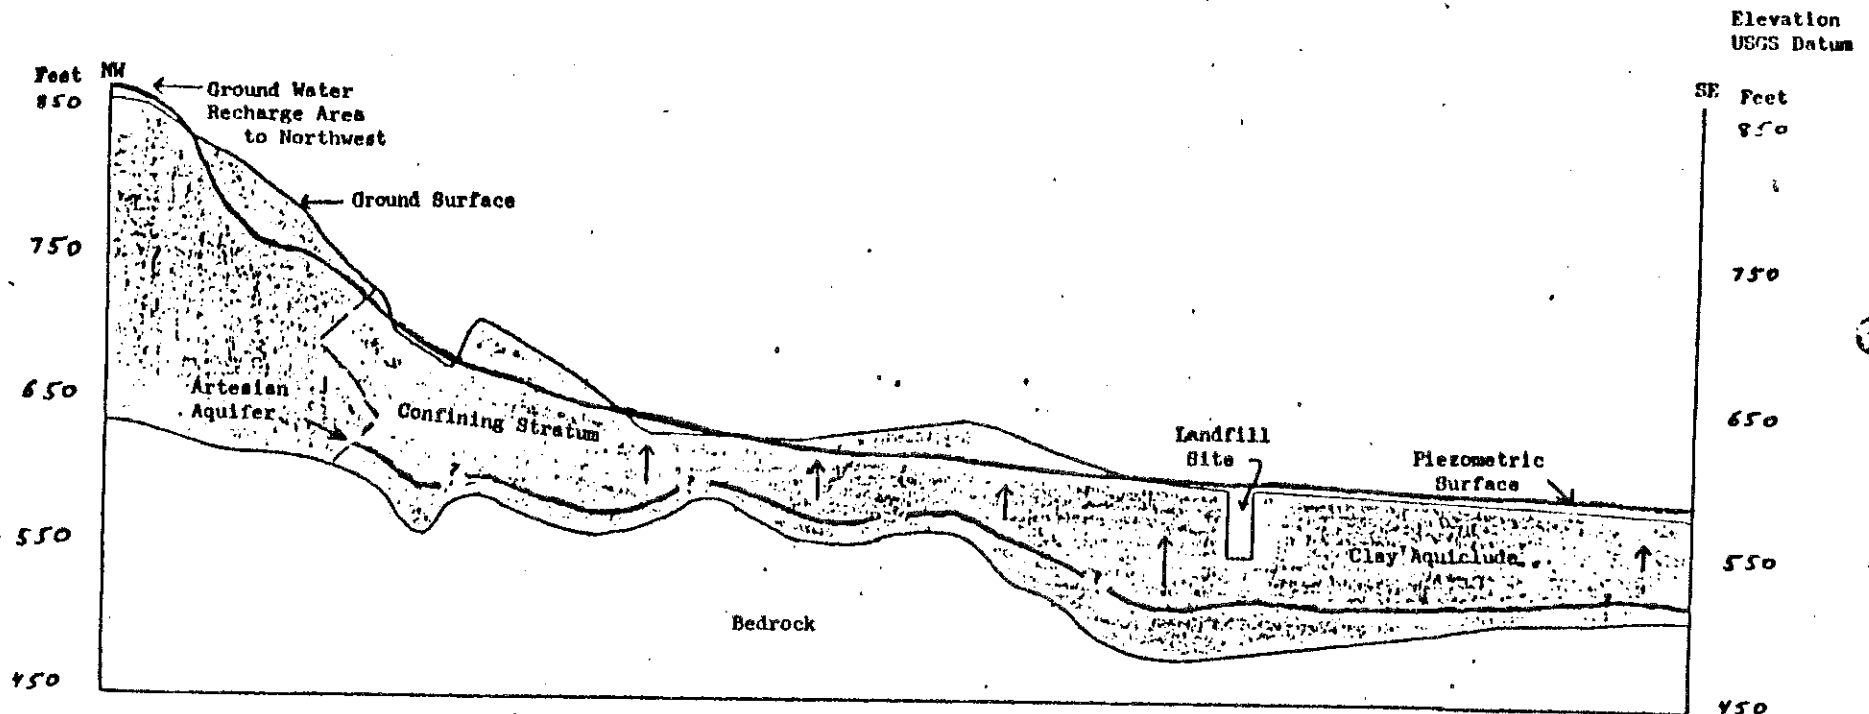

Applicant maintains in his petition for discontinuance (EPA I.D. No. MIT 980568711) that monitoring is not necessary at the site because of a) the dense, uniform clay underlying the site which has a hydraulic permeability no greater than  $6 \times 10^{-8}$  cm/sec and b) the artesian pressure in the underlying aquifer which results in an upward hydraulic gradient across the overlying clay aquitard. Applicant claims that these site conditions will preclude the possibility of leachate migrating downwards out of the landfill and eventually contaminating the aquifer.

In response to this petition, the Wayne County Department of Public Health has raised several questions and concerns (letter from R.N. Ratz, Public Health Engineer, to B. Trethewey, Mining Properties Department, Ford Motor Company, 28 April 1983). The following concerns were raised in the letter:

1. The petition/report fails to address the possibility of leachate migrating down due to differences in densities of the leachate and groundwater.
2. The petition/report does not indicate if there are any organic constituents in the leachate that may increase the clay's permeability and permit downward movement.

The purpose of the present report is to respond to the above stated concerns. Additional information about the geohydrology of the site, about past containment/migration studies, and about the likely nature of the leachate and its effect on clay permeability are evaluated herein to determine the danger of landfill leachate migrating downwards from the site and reaching the underlying aquifer.

## II. THE INFLUENCE OF PERMEANT DENSITY ON LEACHATE MIGRATION ACROSS CLAY BARRIERS

### A. GENERAL

Permeant density plays a direct and indirect role in flow phenomena in porous media. Permeant density can affect solvent or solution flow rates via its influence on hydraulic conductivity. This influence can be calculated and shown to be minor or insignificant compared to the more likely and important influence of permeant density on solute diffusion.

A newly introduced permeant with a high concentration of dissolved material (e.g., a leachate) will also have a higher density. This high concentration in turn will cause the solute to diffuse through a porous medium to regions of lower concentration. It is this manifestation or aspect of a density increase in the permeant that requires careful scrutiny and analysis. In other words, the role and influence of permeant density are more important to solute diffusion under concentration gradients as opposed to solvent (or solution) convection under hydraulic gradients.

The analyses that follow are offered in support of these claims.

### B. INFLUENCE OF PERMEANT DENSITY INCREASE ON HYDRAULIC PERMEABILITY

Both the viscosity and unit weight of a permeant can influence the permeability of a soil to a particular permeant. The hydraulic conductivity is defined in this case as a flow velocity under a unit hydraulic gradient (the usual practice in civil engineering). The influence of permeant density and viscosity can be ascertained explicitly by defining another permeability, i.e., the "intrinsic" or "absolute" permeability

$$K = \frac{k \mu}{\gamma} \quad (1)$$

where:  $k$  = hydraulic conductivity, cm/sec  
 $K$  = intrinsic or absolute permeability, cm<sup>2</sup>  
 $\gamma$  = permeant density or unit weight, dynes/cm<sup>3</sup>  
 $\mu$  = permeant viscosity, poise

The intrinsic permeability( $K$ ) is a property only of the solids or matrix through which the permeant passes. Accordingly, for a particular soil (i.e., given grain size distribution and soil structure) and in the absence of permeant-soil reactions,  $K$  should be a constant. The influence of a variation in viscosity and density of the permeant on the hydraulic conductivity can be determined from this fact and from a relationship derived from Equation 1, viz.,

$$k_2 = k_1 (x_2/x_1) (\mu_1/\mu_2) \quad (2)$$

where:        subscript 1 - initial conditions (grnd water)  
               subscript 2 - final conditions (leachate)

An increase in density of the permeant will apparently cause a higher permeability. But, this same increase in density can also result in an increase in viscosity which will reduce the permeability. Both influences together will tend to offset one another, and it is unlikely that a density increase in the permeant (leachate) will significantly affect hydraulic conductivity. Furthermore, even if viscous retardation is discounted, density increases are highly unlikely to significantly increase permeability in actual practice as the following example will show.

Assume the ground above an aquitard or clay barrier is flooded with a fairly concentrated brine solution, namely sea water. The density of sea water (with a TDS of 36,000 ppm) is 1.036 gm/cc at 4° C vs. the density of the present interstitial water (with an average TDS of 1550 ppm) which is 1.002 gm/cc. This leads to a density ratio of 1.034 which is equivalent to only a 3.4 per cent increase in hydraulic conductivity (discounting viscous retardation). Therefore, density has little effect on hydraulic conductivity despite the almost 20 fold increase in dissolved solids concentration. It is the influence of the latter change, i.e., the increase in dissolved solids concentration, that requires careful analysis in evaluating the effectiveness of a clay barrier in containing leachate migration in this case.

### C. INFLUENCE OF PERMEANT DENSITY INCREASE ON SOLUTE DIFFUSION

#### 1. Background

Dissolved solids or solutes in a permeant can be transported through soils under both hydraulic and concentration gradients. The former is referred to as "drag coupling" and the latter as "chemico-osmotic diffusion." Both types of movement should be considered when evaluating the effectiveness of a clay barrier for preventing leachate migration.

Chemico-osmotic effects in fine grained soils have been examined in some detail by Olsen (1969) and Mitchell et al. (1973). The importance of chemico-osmotic diffusion increases in fine grained soils with low hydraulic conductivities. Studies commissioned by the State of California (1971) on salt intrusion problems in aquifer-aquitard systems have shown that as aquitards become clay rich and their permeabilities fall to levels on the order of .002 gpd/ft<sup>2</sup> or 10<sup>-7</sup> cm/sec, the migration of solutes will be controlled by chemico-osmotic diffusion.

## 2. Flow of Solute under Combined Hydr. and Chem. Gradients

Equations can be derived which describe the flows of solute and solution in the pores of a sediment. The derivation of these equations and assumptions on which they are based are given by Mitchell et al. (1973). The one-dimensional, vertical, steady state flux of solute across a clay aquitard under a combined salt concentration (chemical) gradient and hydraulic gradient is given by the following relationship:

$$J_s = [(\rho_w/RT)C_s k_{ch} + C_s k_h] \partial h/\partial z + [D + C_s k_{ch}] \partial C_s/\partial z \quad (3)$$

where:  $J_s$  = salt flux across an aquitard, moles/sec/cm<sup>2</sup>  
 $\partial h/\partial z$  = hydraulic gradient (dimensionless)  
 $\partial C_s/\partial z$  = solute concentration gradient, moles/cm<sup>4</sup>  
 $D$  = diffusion constant, cm<sup>2</sup>/sec  
 $R$  = gas constant, ergs/mole/°K  
 $\rho_w$  = density of water, dynes/cc  
 $T$  = absolute temperature, °K  
 $C_s$  = average salt concentration, moles/cc  
 $k_h$  = hydraulic conductivity, cm/sec  
 $k_{ch}$  = chemico-osmotic coupling coefficient, cm<sup>5</sup>/mole/sec

Relative contributions to the salt or solute flux can be calculated from Equation 3. Movement of solute can occur by diffusion whether a hydraulic gradient is present or not. A superposed hydraulic gradient may retard or accelerate movement of solute depending on:

- a) Relative magnitude and direction of the hydraulic and solute concentration gradients.
- b) Values of the hydraulic conductivity and chemico-osmotic coupling coefficient.

Equation 3 only yields the steady state flux of solute under combined hydraulic and chemical gradients. Equations can also be derived that give the initial or time dependent solute fluxes and the time required for "breakthrough" or first appearance of increased solute concentration on the downstream side of the aquitard. This initial, non-steady state process is quite complicated. Examples have been worked out for aquitards of different thicknesses and composition by Mitchell et al. (1973).

One of the most important findings of these studies on salt flux across clay aquitards was the importance of aquitard thickness on breakthrough time. Because the initial movement is non-steady, the breakthrough time increases with the square of the thickness of the aquitard. Theoretical studies of salt water intrusion across aquitards (State of California, 1971) have shown that salt ions will

take up to 800 years to migrate across an aquitard 30 feet thick under chemico-osmotic diffusion alone. If the thickness is reduced to 10 feet, the breakthrough time decreases to only 80 years. The presence of an hydraulic gradient could either accelerate or retard this time depending on the relative magnitude and direction of this gradient and other factors cited previously (see Figure 3).

### 3. Likelihood of Solute Efflux Through Clay at Allen Park Site

Solutes will tend to migrate or diffuse downward from the landfill along a concentration gradient. On the other hand, this movement can be impeded or even arrested by the upward hydraulic gradient as a result of artesian pressure in the underlying aquifer. Static water levels in monitor wells around the landfill show that the piezometric surface is almost 10 feet above existing grade or ground surface elevation at the site (see Table 1). The net, steady state flux of solute, if any, can be determined under these conditions from the solute flow equation cited previously (Equation 3).

It is also pertinent to examine the results of a similar type of study commissioned by the State of California (1971). The latter study was designed to determine salt efflux rates and breakthrough times in an aquitard-aquifer system in the coastal ground water basin near Oxnard, California (see Figure 2). The problem posed in the California study was basically the same as the pre-sent one; namely, given a sudden increase in dissolved solids or solute concentration atop a clay barrier (or aquitard) how long before the salt migrated downward and reached an underlying aquifer and at what rates of efflux? The problem was compounded in the California example as a result of drawdown of the piezometric surface in the underlying aquifer which also caused a downward hydraulic gradient.

The two aquitards are quite similar in their important respects. Both are approximately the same thickness, have the same initial dissolved solids concentration, and are composed of clayey sediments with low hydraulic conductivities. The salient characteristics and parameters of these two aquitards are summarized and compared in Table 2. The main difference appears to be in their respective hydraulic conductivities--the Allen Park clay is an order-of-magnitude lower.

A dissolved solids concentration equal to that of sea water was assumed in the leachate overlying the Allen Park clay. Sea water is a good "worst case" choice because sodium ions have high diffusion mobilities and are not preferentially adsorbed on clay exchange sites as heavy

Figure 2. Generalized cross-section of multiple aquifer in a coastal basin. Salt flux across aquitard can occur as result of either salt water intrusion into aquifer (1,2) or salt water entering directly above aquitard in shallow coastal waters or marinas (3,4), or from salt contamination in near surface, perched aquifer (5).

Figure 3. Solute efflux across aquitard into underlying aquifer as a result of salt water intrusion in overlying aquifer. Aquitard is 30 feet thick and has a hydraulic conductivity of  $10^{-7}$  cm/sec. Pumping from lower (Wugu) aquifer superposes a 0.33 downward gradient on system.

metal ions would tend to be. The same chemico-osmotic coupling coefficient used in the California aquitard was also assumed applicable for the Allen Park clay. The value used is reasonable for the type of clay sediments present.

Results of the California study are presented in Figure 3 which shows the salt influx into the underlying aquifer as a function of time. Curves are presented for a no drawdown and 10-foot drawdown case (assuming the hydraulic gradient acts in the same direction as the salt concentration gradient). The horizontal portion of the two curves represents the steady state salt flux.

The main things to notice from this figure are the large breakthrough time (800 years) for the "no drawdown" case (i.e., in the absence of any hydraulic gradients) and the fact that in this aquitard the salt flux caused by drag coupling under a hydraulic gradient is larger. The steady state salt flux from the drag coupling under a combined 10-foot drawdown and salt concentration gradient is almost three times that from diffusion alone (no drawdown). Hence, in the event the hydraulic gradient was reversed, there would be no breakthrough and no downward salt flux provided the upward gradient exceeded about 0.2. In other words, under these conditions the two salt fluxes would be mutually opposed and exactly counterbalanced.

The relative contributions to steady state efflux in this example can be calculated with the aid of Equation 3. The following parameter values (taken from the study) were used in the calculation:

$$\partial h / \partial z \approx \Delta h / \Delta L = 10/30 = 0.33$$

$$\partial c / \partial z \approx (c_{s_2} - c_{s_1}) / \Delta L = \frac{0.57 \times 10}{914} = 0.62 \times 10 \text{ moles/cm}^4$$

$$c_s = (c_{s_2} + c_{s_1}) / 2 = \frac{(0.60 - 0.03) \times 10}{2} = 0.32 \times 10 \text{ moles/cm}^3$$

$$D = 10^{-5} \text{ cm}^2/\text{sec}$$

$$R = 8.32 \times 10^7 \text{ ergs/mole/}^\circ\text{K}$$

$$T = 300^\circ\text{K}$$

$$\gamma_w = 10^3 \text{ dynes/cc}$$

$$k_h = 10^{-7} \text{ cm/sec}$$

$$k_{ch} = 6.2 \times 10^{-4} \text{ cm}^5/\text{mole/sec}$$

Using these values the calculated contributions to steady state solute flux are respectively:

Drag Coupling:  $J_{s_1} = [(\gamma_w/RT)c_s k_{ch} + c_s k_h] \partial h/\partial z$

$$= \left\{ \frac{10^3 (2 \times 10^{-7})}{8.32 \times 10^9 (.3 \times 10^{-3})} + 0.32 \times 10^{-3} (10^{-7}) \right\} 0.33$$

$$= 1.056 \times 10^{-11} \text{ moles/sec/cm}^2$$

$$= \underline{0.98 \times 10^{-8} \text{ moles/sec/ft}^2}$$

Chemico-Osmotic Diffusion:

$$J_{s_2} = [D + c_s k_{ch}] \partial c_s / \partial z$$

$$= [10^{-5} + 2 \times 10^{-7}] 0.62 \times 10^{-6}$$

$$= 0.63 \times 10^{-11} \text{ moles/sec/cm}^2$$

$$= \underline{0.58 \times 10^{-8} \text{ moles/sec/ft}^2}$$

The total salt flux is the sum of the contributions from drag coupling and chemico-osmotic diffusion or

$$J_s = J_{s_1} + J_{s_2}$$

$$= (0.98 + 0.58) \times 10^{-8}$$

$$= \underline{1.56 \times 10^{-8} \text{ moles/sec/ft}^2}$$

These calculations are in agreement with the results shown in Figure 3 for steady state salt inflow under combined gradients. They also illustrate that the drag coupling contribution under a 10-foot drawdown (0.33 hydraulic gradient) exceeds the chemico-osmotic diffusion contribution.

In the case of the clay aquitard beneath the landfill at Allen Park, the average hydraulic conductivity is almost an order-of-magnitude lower ( $2.6 \times 10^{-8}$  vs.  $10^{-7}$  cm/sec). This will tend to decrease the drag coupling. On the other hand, this tendency will be more than offset by higher hydraulic gradients at this site. If the level of the leachate is kept at or close to the bottom of the landfill, then the gradient will approach 80/30 or 2.7. The drag coupling component of solute flux in this case will be

$$J_{s_1} = \left[ \frac{10^3 (2 \times 10^{-7})}{8.32 \times 10^9 (.3 \times 10^{-3})} + 0.32 \times 10^{-3} (2.6 \times 10^{-8}) \right] \times 2.7$$

$$= [0.008 \times 10^{-12} + 0.832 \times 10^{-11}] \times 2.7$$

$$= 2.25 \times 10^{-11} \text{ moles/sec/cm}^2$$

$$= \underline{2.09 \times 10^{-8} \text{ moles/sec/ft}^2}$$

This flux is greater than 3X the chemico-osmotic flux; and since it acts in the opposite direction, there will be no net downward flux of solute at the Allen Park site. The critical hydraulic gradient to maintain a zero net salt efflux is 0.8. This means that the groundwater table could rise to within 12 feet of present ground elevation (~595 ft) in the landfill and there would still be a sufficient upward hydraulic gradient (drag coupling effect) to completely counter solute efflux under chemico-osmotic diffusion (see summary below).

| <u>Position of Ground<br/>Water Table in the<br/>Landfill</u> | <u>Upward<br/>Hydraulic<br/>Gradient</u> | <u>Net, Steady State<br/>Solute Efflux Rate<br/>(moles/sec/ft<sup>2</sup>)</u> |
|---|--|--|
| At bottom   | 2.7                                      | $-1.51 \times 10^{-8}$<br>(net influx)   |
| 12 feet from top  | 0.8                                      | zero   |
| At top  | 0.33                                     | $+0.32 \times 10^{-8}$   |

These calculations are based on the existence of a static or piezometric head in the underlying aquifer approximately 9-10 feet above ground elevation (see Table 1).

Assumption of worst case conditions, namely, a rise in the groundwater table in the landfill to ground surface elevation, leads to a small, steady state efflux rate from chemico-osmotic diffusion. This occurs because the resulting hydraulic gradient (0.33) is no longer large enough to completely oppose the chemico-osmotic salt flux. The breakthrough times, however, would be so immense (1000's of years) that the steady state flux under these conditions is largely irrelevant.

It is important to note that the preceding calculations are also based on the following "worst case" assumptions:

1. A highly saline leachate with a concentration and composition equal to that of sea water.
2. No interaction between the solute and clay.

In actual practice, there would be some uptake and adsorption of solutes on the clay. This adsorption would attenuate or limit further solute concentrations in the leachate as it passed through the clay.

### III. EFFECT OF LEACHATE CONSTITUENTS ON THE PERMEABILITY OF CLAY

#### A. GENERAL BACKGROUND

The possibility that leachate--either in the solvent or solute phase--might affect clay permeability and hence its containment integrity has been raised by a number of investigators (Anderson and Brown, 1981; Haxo, 1981; and Folkes, 1982). One of these studies has shown that concentrated organic liquids can increase clay permeability by several orders-of-magnitude (Anderson and Brown, 1981).

All of these studies were conducted in the laboratory with simulated leachates from particular types of wastes and under particular testing conditions. The danger of blindly applying these test results to a field situation have been noted recently by Gray and Stoll (1983). It is essential to ask the following before the results of these lab tests can be applied to a given field situation:

1. What was the nature of the leachate in the lab tests? What are the concentrations of various constituents in the leachate in the field as opposed to the lab tests? How relevant are the lab test results in the light of potentially large differences in leachate composition (lab vs. field)?
2. How did the leachate contact or interact with the clay in the lab tests? Was it forced through? If so, at what gradient? Is there any prospect that the leachate will be able to penetrate/permeate through the clay containment in the field in like manner? In other words are the necessary gradients and other conditions present to permit this to happen?
3. What was the failure or clay degradation process by which the apparent permeability increase occurred in the lab tests? Was it by a) dissolution, b) syneresis, c) piping? Could these mechanisms reasonably occur in the field given the type, water content, and density of the in-situ clay plus the nature and concentration of organic and inorganic compounds in the leachate?

#### B. WASTE AND LEACHATE COMPOSITION AT THE ALLEN PARK CLAY MINE

The types, composition, and relative amounts of wastes placed in the Type II Solid Waste Landfill at Allen Park are shown in Tables 3 and 4. The results of typical E.P.T leachate tests on these wastes are shown in Table 5. The likely nature and composition of the landfill leachate can be estimated from this information. This estimate is adequate for purposes of evaluating the probable effect of the leachate on clay permeability.

TABLE 3. ALLEN PARK CLAY MINE - SOLID WASTE  
LANDFILL CONSTITUENTS

|  |   |      |

March 1, 1975

The data in Tables 3 and 4 indicate that 50 per cent of the solid waste consists of relatively inert fly ash and that some 89 per cent of the wastes consist of materials that do not contain significant amounts of heavy metals (Zn, Pb, Cd) or organics known or suspected to be toxic such phenol and naphthalene (see Table 4). The coke oven decanter tar sludge is a possible source of organics (phenol and naphthalene), but this waste comprises only 0.6 per cent of the total stream in the Type II Solid Waste landfill.

### C. PROBABILITY OF ORGANICS IN LEACHATE AFFECTING CLAY PERMEABILITY AT ALLEN PARK SITE

Anderson and Brown (1981) found that several organic liquids, viz., aniline, acetone, ethylene glycol, heptane, and xylene, cause large increases in permeability of four compacted clay soils. Pure organic liquids were used in their study. One of the authors (Anderson, 1982) later emphasized that their results cannot be used to support claims that clay liners permeated by dilute organic liquids may be susceptible to large permeability increases.

Haxo (1981) reported results of up to 52 months of liner exposure to selected industrial wastes. He included several organic wastes, namely, aromatic oil, Oil pond 104, and a pesticide. The results of large permeameter tests on a compacted fine-grained soil and admixed materials are summarized in Table 6. Although a small amount of seepage passed through the compacted, fine-grained soil liner, no permeability increases were reported with any of the organic wastes.

On the basis of these studies and with the caveats noted at the beginning of this section in mind, it is possible to evaluate the likely effect of the landfill leachate on clay permeability at the Allen Park site.

#### 1. Type II Solid Waste Landfill

As noted previously the existing landfill contains small quantities of coke oven decanter tar sludge which is a possible source of organics (phenol and naphthalene), but this waste comprises only 0.6 per cent of the total. Phenol and naphthalene are present in the tar component of this waste in concentrations estimated by Desha (1946) of 0.1 and 2.2 per cent by weight respectively. Accordingly, the amount of phenol and naphthalene present in the total waste stream are .006 and .013 per cent by weight respectively. These amounts constitute a very low fraction and they suggest that leachate from the total waste stream will tend to have very low concentrations of phenol and naphthalene. Therefore, the organics in the leachate from the Type II Solid Waste landfill are quite unlikely to affect clay permeability.

## 2. Type I Hazardous Waste Landfill

In the future the decanter tar sludge will be placed in a separate landfill that will be upgraded to accept hazardous wastes. This action will increase the relative proportion of organics (phenol and naphthalene) in the waste stream. Leachate tests run on pure samples of decanter tar sludge using a distilled water extraction procedure (Calspan, 1977) have produced phenol concentrations of approximately 500 ppm. Even this concentration is far removed from the very high concentrations of organic solvents used by Anderson and Brown (1981) in their permeability tests on different clays. Accordingly, organics in the leachate from the Type I Hazardous Waste landfill are also unlikely to affect clay permeability.

In summary: It does not appear likely nor reasonable that organics present in the wastes at the Allen Park Clay Mine/Landfill will cause a permeability increase given their low concentration and the absence of any substantiation in the published technical literature for such an increase under these conditions.

#### IV. CONCLUSIONS

- (1). There appears to be very little likelihood of leachate migrating downward from the Allen Park Clay Mine/Landfill and contaminating the aquifer beneath the clay.
- (2). A density difference between the leachate and groundwater will have little or no influence on hydraulic permeability or downward migration nor will it lead to diffusion efflux of solutes. A thick, uniform bed of silty clay beneath the site coupled with an upward hydraulic gradient precludes the latter. Calculations and analyses are provided herein to support this finding.
- (3). Comparison with results of salt water intrusion studies across clay aquitards having similar properties as the clay beneath the Allen Park Clay Mine site show that the solute (salt) will take at least 800 years to migrate across a clay barrier 30 feet thick under chemico-osmotic gradients alone. A counter (or upward) hydraulic gradient will increase this breakthrough time even more.
- (4). The waste and its leachate are unlikely to increase the permeability of the underlying clay. This claim is reasonable in view of the low concentrations of organics in the total waste stream and in the light of the findings and caveats of permeability/exposure tests with organic permeants reported in the technical literature. This conclusion applies to both the existing Type II Solid Waste landfill and a proposed Type I Hazardous Waste landfill that will accept the coke oven decanter tar sludge.
- (5). The composition of the waste and underlying clay do not suggest properties or combination of properties that could lead to a containment failure caused by such processes as piping, acid/base dissolution, or syneresis.
- (6). Under these circumstances any observed increase in contaminant levels of monitor wells in the aquifer underlying the site could just as well come from other sources laterally upgradient from the site rather than from the clay mine/landfill above the site.
- (7). These findings and conclusions support the basis of applicant's petition for discontinuing further monitoring of the wells penetrating the aquifer beneath the site.

RE: Allen Park Clay Mine/Landfill

Dear Mark:

I recently wrote a computer program (\*CLAYWALL\*) that can be used to calculate solute transport across a clay barrier under combined diffusion and advection (hydraulic flow). The program computes the exit/source concentration ratio ( $C/C_0$ ) as a function of elapsed time ( $t$ ) on the downstream side of a clay wall or barrier of thickness ( $X$ ).

The program was written with a clay slurry cut-off wall in mind, but is general enough that it can be used with any clay layer or barrier. The input parameters to the program are:

$D_e$  = effective diffusion coefficient,  $\text{ft}^2/\text{yr}$   
 $K$  = hydraulic permeability,  $\text{ft}/\text{yr}$   
 $X$  = thickness of wall or barrier,  $\text{ft}$   
 $P$  = porosity  
 $I$  = hydraulic gradient... (+) if same direction,  
(-) if opposite direction to solute concentration gradient  
 $t$  = elapsed time, yrs

The program is based on the solution to the equation that describes one-dimensional solute transport in a saturated porous medium under both hydraulic and solute concentration gradients. This equation has the following form:

$$C/C_0 = 0.5[\text{erfc}((X-vt)/\text{sqr}(4DK)) + \exp(vX/D) \text{erfc}((X+vt)/\text{sqr}(4DK))]$$

where:  $v$  = ave seepage velocity =  $(KI/P)$

The solution assumes the following conditions:

1. Saturated, one-dimensional flow.
2. No reaction between solutes and porous medium. Chloride typically behaves this way.

3. Diffusion controlled, i.e., the pore water velocity is so low that mechanical mixing is negligible and the dispersion is equal to the effective diffusion coefficient. (this condition is satisfied when  $K < 1.0E-07$ ).

I ran the program using data for the silty clay layer underlying the Allen Park ClayMine/Landfill. The following values for the input data were used:

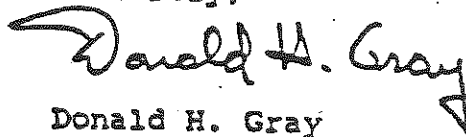

$D = 0.102 \text{ ft}^2/\text{yr}$  ( $6.3E-06 \text{ cm}^2/\text{sec}$ )  
(published value for clay tills)  
 $K = 0.025 \text{ ft/yr}$  ( $2.5E-08 \text{ cm/sec}$ )  
 $X = 30 \text{ ft}$   
 $P = 30 \%$   
 $I = -0.1, -0.3, \text{ and } -1.0$

The results of the analysis are shown in the attached graph. At a counter hydraulic gradient of  $-0.3$  the exit/source solute concentration ratio does not exceed  $0.0001$  until 700 years have elapsed. You may recall that a counter hydraulic gradient of  $-0.3$  occurs when the leachate is allowed to rise in the landfill to the ground surface...a worst case scenario. For larger (negative) counter hydraulic gradients the ratios become even smaller. In fact for  $I < -0.5$  (i.e., counter hydraulic gradients larger than  $0.5$ ) the ratio  $C/C_0$  is less than  $1.0E-05$  at all elapsed times.

These results confirm the findings of my earlier report which were based largely on analogy to solute transport studies in clay aquitards. The present findings are based on analysis of actual soil and site parameters. Keep in mind, also, that the analysis is still quite conservative because it neglects possible adsorption (reaction) of solutes with the clay.

A copy of the computer program and typical output are enclosed. It is written in BASIC and is designed to be run on a personal computer. If you have any questions about the analysis, please feel free to contact me.

Sincerely,

Donald H. Gray  
Professor of Civil Engineering

RE: Allen Park Clay Mine/Landfill

Dear Dave:

I have reviewed the memorandum dated January 23, 1984, from Terry McNeil, Technical Services Section, to Larry Aubuchon, Compliance Section, Detroit District, MDNR. The memorandum essentially raises the following objections to the findings and conclusions in my report, viz.,

Objection 1. There is no substantiation nor literature citations to show that organics present in the waste will not increase permeability.

Objection 2. The presence and possible effects of naphthalene in the waste are disregarded.

Objection 3. Uncertainties remain about the actual composition and likely nature of the leachate.

Objection 4. The report does not address the question of compatibility between the following:

- a) Leachate and leachate collection system components
- b) Generated gases and clay cap.

In the opinion of the MDNR reviewer Objections 1,2, and 3 taken together mean that Specific Condition 5.A.4 (a) of Act 64 license is not satisfied. The reviewer goes on to say, however, that they (MDNR) would accept compatibility testing between actual leachate being generated and the on-site clay being used for containment. I will respond herein to these stated objections and opinion. Objection 4 which pertains to Specific Condition 5.A.4 (b) and (c) is outside the scope and original charge of my investigation.

Objection 1 is a version of the "guilty until proved innocent" syndrome. I understand and even sympathize with this approach in matters which deal with the release of potentially hazardous substances into the environment. There is, however, considerable substantiation in the published technical literature for the contention that organics present in low concentrations in aqueous leachate will not increase the permeability of dense clays.

Leachate permeability tests on sand-clay columns packed to bulk densities within the range of densities of natural clays (Cartwright *et al.*, 1977) have shown that permeability actually decreased with passage of leachate (containing organics). These tests were continued for periods up to nine months. Decreases were even more pronounced for raw, unsterilized leachate. In addition to permeability reduction from the passage of leachate, Griffin and Shimp (1976) have shown that heavy metal ions (Pb, Zn, Cd, Hg) are strongly attenuated by clay. Organics that were present in the leachate were only moderately attenuated by the clay; they did not increase hydraulic conductivity. We have also conducted long term leachate permeability tests ourselves on a silty clay almost identical in composition to the clay underlying the Allen Park Clay Mine/Landfill site (Gray, 1982) and found the same results, i.e., no increase in permeability was observed. A chemical analysis of the leachates used in all these permeability tests is attached. Note the presence of naphthalene in one of the leachates--a constituent whose presence and influence the MDNR reviewer claimed we had not considered. [Note: Cited references are listed in an attachment to this letter report.]

It is important to emphasize again the fact that leachate permeability tests conducted by Anderson (1982) are totally unrepresentative of conditions at the Allen Park site. These tests are often cited as an example of the deleterious influence of organic solvents on clay liner permeability. Anderson's tests are unrepresentative and irrelevant for the following reasons:

1. He used pure organic solvents. The leachate at the Allen Park Clay Mine/Landfill will be an aqueous extract containing very low concentrations of organics.
2. He forced the solvents through clays at extremely high, positive gradients. Anderson used positive gradients ranging from 60 to 300. At the Allen Park site there will be negative (reverse) gradients ranging on the order of -0.3 (worst case) to -2.7.

Other objections can also be cited in regard to Anderson's test procedures and results. He used a rigid wall permeameter which permits channeling between sample and container. The recommended procedure to avoid this potential problem is to use a flexible, pressurized jacket. Large reported increases in permeability should be viewed with some skepticism when rigid wall permeameters have been employed.

Green *et al.* (1981) have investigated in great detail the characteristics of organic solvents that affect their rate of movement (permeability) in compacted clay. They measured the equilibrium permeability of three clays (a clay shale, a fire clay, and kaolinite) to the following solvents: benzene, xylene, carbon tetrachloride, trichloroethylene, acetone, methanol, glycerol, and water. Their study showed that it is the hydrophilic or

hydrophobic nature of the solvent (as measured by the octanol/water partitioning coefficient or roughly by the dielectric constant) and not the viscosity/density ratio that is important in predicting a solvent's rate of flow through clays. According to their findings water, which has a high dielectric constant, always exhibited the highest permeability. In addition, they found that the packed clay density is crucial in determining how permeable a clay will be to a given solvent. At high bulk densities (on the order of 115 pcf or 1.85 g/cc) the solvent characteristics became less important in differentiating permeability response.

Green et al. (1981) also observed that solvents of low dielectric constant (e.g. xylene and carbon tetrachloride) tended to cause shrinkage and cracking of some of the clays. This phenomenon, known as syneresis, can and eventually did cause an apparent permeability increase in some of the clays that were tested. The same phenomenon was reported by Anderson (1982) in some of his experiments. It must be emphasized again, however, that the effect has only been observed and reported when several pore volumes of pure, low-dielectric organic solvents are forced at very high gradients through clay columns. These conditions simply do not occur at the Allen Park Clay Mine/Land-fill site.

On the contrary, the conditions at the Allen Park site are ideal for effective containment, viz.,

1. The site is underlain by a thick ( $X \geq 25$  ft) section of dense, competent silty clay ( $\gamma_p = 115$  pcf) with a very low hydraulic conductivity ( $k = 2 \times 10^{-8}$  cm/sec)
2. A negative hydraulic gradient exists at the site as result of artesian conditions in the underlying aquifer. Even under worst case assumptions (viz., leachate levels rising to the top of the landfill) a negative gradient of -0.3 will still be present.
3. The leachate consists of very low concentrations of organic and inorganic solutes in an aqueous solution as opposed to a pure solvent.

Under these conditions advective transport or hydraulic seepage ceases to dominate pollutant movement across a clay barrier (see Gilbert and Cherry, 1983; Tallard, 1984). Instead, diffusion under chemical concentration gradients becomes more important, and it is this transport mechanism that must be evaluated carefully. I have dealt with this problem both in my original report and in my subsequent letter report to Mr. Mark Young, Wayne Disposal, Inc., dated 25 September 1983. I showed that even under worst case assumptions of no partitioning or attenuation of pollutants and minimum, negative hydraulic gradients breakthrough times would be on the order of thousands of years. Interestingly, if the calculations are repeated allowing the

hydraulic conductivity or permeability to double or even triple, the breakthrough time increase even more because now the counter advective flow is more effective in opposing the downward diffusion of solutes along their concentration gradient.

I come now to the MDNR comments about requiring compatibility testing (whatever that means) between actual leachate and the clay liner material. Unfortunately, the procedure, rationale, etc. for such tests are not specified. What is being required ...that the leachate be forced under high hydraulic gradients through a thin sample of the silty clay? The results or significance of such a test would be ambiguous at best and meaningless at worst in this case. In my opinion, such tests would be an exercise in futility and irrelevance given the condition and circumstances at the Allen Park Clay Mine/Landfill site.

Breakthrough times in diffusion controlled transport are extremely sensitive to thickness of the barrier. In order to replicate conditions in the field at Allen Park, compatibility or flow tests should be run on a sample column 25 feet high under a negative gradient no less than -0.3. After a wait time of thousands of years such a test would merely confirm what is already demonstrable.

It is my professional opinion that in this instance the requirement for compatibility testing and concern over permeability is a diversion from the real issue which is the likelihood of diffusion transport of solute across the clay. I have shown that this will not be a problem at the Allen Park Clay Mine/Landfill site because of the thickness, competency, and density of the underlying clay together with the existence of a negative gradient.

I find it baffling that MDNR can approve a thin, clay slurry wall for a toxic waste site (see Consent Judgment, U.S. District Court, U.S. Envl. Protection Agency and The State of Michigan, Plaintiffs, vs. Velsicol Chemical Corp., Defendant) based on meagre and inadequate evaluation whilst insisting on irrelevant tests for a thick, natural clay containment system at Allen Park that is ideal in nearly every respect.

Sincerely,

*Donald H. Gray*

Re: Allen Park Clay Mine Seismic Survey

Dear Mr. Miller:

As per your request a seismic study was performed at the Allen Park Clay Mine area in Allen Park, Michigan. The purpose of this study was an attempt to determine the depth to bedrock in the area immediately below the excavated pit at the disposal area.

Keeping consistent with previous seismic work accomplished in the area these stations were numbered 4, 5 and 6. Stations 4 and 5 were completed on the excavated pit floor, 4 being on the eastern half and 5 on the western side of the pit floor, with station 6 directly to the north of the pit up on approximately the existing surface elevation, some 30 to 40 feet above the pit floor. Plots of the data collected are included and indicate both the velocities of the layers and the depths to the layer interfaces.

Station 4 resulted in the best data collected at the site, and shows a three-layer case. A low velocity (1428 ft/sec) layer is underlain by a very consistent layer with a velocity of 5233 ft/sec, extending to a depth of 57 feet below the pit floor where it is underlain by a much higher velocity (12,808 ft/sec) layer. These values are very typical of a dense clay layer underlain by a hard limestone type material. The rather good fit of the data to a line would indicate very consistent materials, however, the irregularities near the 57 foot contact indicate that this interface is not as sharp a transition and hence it represents more of a minimum depth to this interface.

At Station 5 area surface topography was rough and inconsistent which resulted in limited data being collected. In one area a very steep depression was encountered on the surface which the shock wave source worked in. This abrupt lowering of the elevation causes a decrease in the time it takes to the shock wave to travel through the subsurface. Therefore, the best fit line was drawn through only those points where the shock wave source was at the approximate same elevation. Had the elevation been consistent, the travel times for those distances, which were lower, would have been increased in the direction towards this line.

L. M. Miller & Associates

July 17, 1982

Page 2, 1982

Station 5 showed approximately the same subsurface conditions as did 4, with a depth to the bedrock being indicated at 70 feet below the pit floor. Station 6 was run at a much higher elevation than that of the pit floor, and very soft wet surface conditions were found. These types of surface conditions do not allow for seismic shock waves to propagate as the material tends to absorb much of the energy and transmit this energy directly across the surface rather than down into the earth. This data indicates again a rather consistent layer with a velocity typical of a dense clay. As a rule of thumb, seismic tests measure in depth roughly one-third the distance from the energy source to the geophone. Using this rule the limits of our data would be to a depth of approximately 45 feet for the clay layer and would obviously extend until the next layer is encountered.

We hope that this information is useful to you. If any further information on subsurface conditions is needed, it should be noted that there is enough room in the bottom of the excavated pit for an electrical resistivity test to be run. The problems caused by surface conditions could be avoided and with the large contrast in the subsurface materials this test would most likely work well.

If we can be of any further assistance, please let us know.

Very truly yours,

L. M. MILLER & ASSOCIATES

RE: Permeability testing of clay soils  
 Allen Park Clay Mine; Allen Park, Michigan  
 Wayne County

Dear Marshall:

Based on the review of the soil tests performed (grain size analysis, atterberg limits and permeability) on the clay at the Allen Park Clay Mine Landfill, it is the feeling of this office that the materials are uniform enough that no further permeability testing will be required. This portion of our evaluation has been satisfied with the information submitted.

If you have any questions, please feel free to call.

Very truly yours,

RESOURCE RECOVERY DIVISION

E-3 Aquifer Identification 40 CFR 270.14(c)(2)

There are two sand formations on site. The uppermost formation is a beach sand deposit that varies from 0-8' in thickness but is limited in regional extent due to excavations and construction projects in the vicinity. These sands are water bearing when the perimeter surface drain is in a state of efflux.

Since this formation lies above the disposal cell lined walls, there is no potential for migration of leachate from the regulated unit into this formation. Under these conditions, the provisions under 40 CFR 270.14(c)(2) thru 270.14(c)(8) do not apply.

The uppermost aquifer is then identified as being the sand formation lying approximately 80 feet below grade.

E-4 through E-8 not applicable per E-1.

Section F -  
Procedures to Prevent  
Hazards

6. Storm Water - Insure that storm water collected in the inactive areas does not come in contact with active work areas. Inspect integrity of diversion berms in the cell in order to maintain separation of active from inactive work areas. Inspect run-on and run-off diversion berms and dikes for erosion or general damage that would allow water into the waste management area.
  
7. Leachate System - Inspect record and sample the following system components.
  - a) Primary and Secondary Pump Systems.
    1. Switching mechanisms operable.
    2. Pumps operable.
    3. Verify liquid volumes in sump.
  - b) Primary Leachate Holding Tanks.
    1. Monitor secondary containment.
    2. Monitor leachate volume.
    3. Sample leachate (if necessary).
  - c) Secondary Holding Tanks
    1. Monitor liquid volume.
    2. Sample and analyse liquid (if necessary).
  - d) Discharge Lines.
    1. Inspect for damage (clean-outs)
  - e) Sampling Manhole.
    1. Proper flow recording.
    2. Proper leachate discharge.

F-2

General Inspection Requirements 40 CFR 270.14(b)(5)

F-2b

Landfill Inspection 40 CFR 264.303(b)

The general inspection schedule and the inspection procedures for the facility are provided in Attachment 18. The backside of the inspection schedule is used for detailed notations and explanations or observations. The inspector initials the items which were checked and provides the date and time of inspections.

F-3

Equipment Requirements 40 CFR 270.14(b)(6)

The hazardous wastes handled at the facility are not considered to be "acutely toxic". Accordingly, an internal communications or alarm system is not necessary. A telephone is available for external communications at the manifest office trailer for summoning general emergency assistance. The hazardous waste management area is in view from the manifest office trailer. Fire extinguishers are available for the manifest office trailer and mobile equipment. Water is available on site in ditches and the pond as well as a fire hydrant. The wastes disposed of are not flammable. Due to the facility layout, aisle space requirements have been met.

## Hazardous Waste

## General Inspection Procedures

## Ford Motor Company - Allen Park Clay Mine Landfill

A. Surveillance Schedules and Procedures

During hours of operation, surveillance is the responsibility of the supervising inspector, check-in trailer staff as well as operators at the active fill area. In addition, the landfill is periodically patrolled by Ford security personnel. During hours when the site is closed, the only entry gate is locked preventing unauthorized entry. Refer to Site Security Plan.

B. Routine Maintenance Procedures and Schedules

To minimize the possibility of unplanned sudden or non-sudden releases of hazardous wastes or hazardous waste constituents to air, soil or water, routine facility inspections are conducted and maintenance performed as required. The following checklist is utilized:

Daily Items - Monday Through Friday and After Storms

1. Proper Disposal - Insure that proper wastes are unloaded and landfilled in the appropriate location.
2. Gate Security - Insure the proper functioning of the gate and lock.
3. Access Road - Inspect the road for repairs, proper cleaning or dust suppression.
4. Warning Signs - Insure that appropriate warning signs are visible.
5. Daily Cover - Insure that cover material is available and that incoming wastes are covered daily.

Section F Procedures to Prevent Hazards

F-1      Security Procedures    40 CFR 270.14(b)(4)

We believe that physical contact with the wastes, structures or equipment within the active portion of the facility is not likely to injure unknowing or unauthorized persons or livestock. However, security measures have been taken in satisfaction of 264.14(b)(2) and (c) as stated in the Site Security Plan (Attachment 17).

FORD MOTOR COMPANY ALLEN PARK CLAY MINE

MID 980568711

SITE SECURITY PLAN

1. All entry to the facility is through one main gate located off Oakwood Boulevard, between Interstate 94 and Southfield Freeway. During hours of operation, all vehicles and visitors must pass by an attended check-in trailer for entry.
2. The operational hours for the hazardous waste site is 7:00 a.m. to 3:00 p.m., Monday through Friday. The solid waste site is open 16 hours per day, Monday through Friday.
3. A six foot cyclone fence topped with three strand barbed wire has been constructed around the entire perimeter of the site. Surface water drains and large screening berms on the site perimeter further impede unknowing or unauthorized entry by persons or animals.
4. Warning signs that read "No Trespassing - Violators will be Prosecuted" are affixed to the perimeter fence at intermittent spacing which will discourage unauthorized entry.
5. Physical contact with the wastes, structures, or equipment with the active portion of the facility will not injure unknowing or unauthorized persons or livestock which may enter the active portion of the facility.
6. Warning signs that read "Danger Unauthorized Personnel Keep Out" are posted at each entrance to the active portion of the facility in

sufficient numbers to be seen from any approach to the active area.

7. Entrance gate is locked by manifest checker when facility is closed.
8. Ford Motor Company Rouge Plant Security provides additional security coverage on an inspection audit basis.

8. Bulldozer - Insure bulldozer is operable.
9. Telephone - Insure operation of phone.

#### Weekly Items

1. Fire extinguishers - Check the availability and pressure gauges on the fire extinguishers. Extinguishers are in Manifest Trailer and mobile operating equipment.
2. Gauze Masks - Verify that the gauze masks are available.
3. Perimeter Fence - Look for locations where the fence is in disrepair.
4. Surface Drains - Look for blocked drainage and surface water contamination.
5. Sediment Basin - Check the outflow for blocked drainage and surface water contamination.
6. Intermediate cover - Inspect all fill areas that do not have final cover to insure that intermediate cover is adequate. Inspect for erosion or other damage that could or has exposed wastes.

#### Quarterly Items

1. Monitor Wells - Inspect integrity of protective casings, including caps and locks.
2. Final cover - Inspect all areas which have received final cover for deep rooted vegetation, deterioration of vegetative cover, areas of surface erosion and other surface disturbances.
3. Fire Hydrant - Inspect for vandalism.

-over-

F-4 Preventive Procedures, Structures, and Equipment 40 CFR 270.14(b)(8)

F-4a Unloading Operations 40 CFR 270.14(8)(i)

The unloading operation consists of tipping the truck box which requires level ground. The bulldozer operator is responsible for providing a level dump area within the waste management unit.

F-4bc Run-Off/Water Supplies 40 CFR 270.14(b)(8)(ii)(iii)

The topography of the area as shown on the Engineering Drawings (Attachment 14) prevents run-off by collecting any storm waters in the cell excavations as run-on. Contaminated water is not discharged to surface drains but is treated. The area is served by city water provided by Detroit Water and Sewerage Department.

F-4d Equipment and Power Failures 40 CFR 270.14(b)(8)(iv)

A spare pump will be kept at the facility to replace a pump in times of mechanical failure. Heavy equipment and portable generators are also available at the Rouge Complex in case of mechanical or power failure.

F-4e Personnel Protection Equipment 40 CFR 270.14(b)(8)(v)

Operators are not required to wear protective clothing except for safety shoes, due to the relatively innocuous nature of the waste involved. Gauze masks are provided to operators for handling K061 if they do not operate in an enclosed cab.

F-5 Precautions to Prevent Ignition or Reaction of Ignitable or Reactive Wastes 40 CFR 270.14(b)(9)

Ignitable, flammable, reactive, or incompatible wastes are not handled at the facility.

Section 6 -  
Contingency Plan

August 16, 1988

Section G CONTINGENCY PLAN 40 CFR 270.14(b)(7)

G-1 General Information

The hazardous waste disposal facility consists of 16.5 acres in the northeast corner of the site as shown on the site plan. The site address is 17005 Oakwood Boulevard, Allen Park, Michigan 48101, and the site mailing address is Ford Motor Company, and 15201 Century Drive, Suite 608, Dearborn, Michigan 48120.

Waste types to be disposed of at the facility are:

- . (K061) Electric Furnace Emission Control Dust
- . (K087) Decanter Tank Tar Sludge from Coking Operations
- . (F006) Wastewater Treatment Sludge from Electroplating Operations
- . (D004) EP Toxic - Arsenic
- . (D005) EP Toxic - Barium
- . (D006) EP Toxic - Cadmium
- . (D007) EP Toxic - Chromium
- . (D008) EP Toxic - Lead
- . (D009) EP Toxic - Mercury
- . (D010) EP Toxic - Selenium
- . (D011) EP Toxic - Silver
- . (001D) EP Toxic - Copper
- . (003D) EP Toxic - Zinc

G-3 Implementation 40 CFR 264.52(d)  
40 CFR 264.55

The contingency plan will be implemented by the emergency coordinator when an imminent or actual hazard incident could threaten human health and/or the environment. Example of such hazards could be fire, fumes, dike failure, or storm overflow.

G-4a Emergency Contacts and Notification Procedures 40 CFR 264.56(a)

Any unplanned release of hazardous waste to the soil, air or surface water at the facility which could threaten human health or the environment would warrant implementation of this plan, as well as any condition which if not corrected might cause such a release. The above

emergency coordinator(s) should be contacted if the plan must be implemented, and additional emergency numbers for locally available help are provided as follows:

|  | <u>Area Code (313)</u> |
|--|------------------------|
| 1. Ford Plant Security.....                          | 322-3211               |
| 2. Allen Park Fire Department.....                   | 928-4100               |
| 3. Allen Park Police Department.....                 | 386-7800               |
| 4. Wayne County Sheriff.....                         | 224-2222               |
| 5. Michigan State Police.....                        | 256-9636               |
| 6. E.M.S. (Taylor).....                              | 295-3300               |
| 7. Pollution Emergency Alerting System (D.N.R.)..... | 1-800-292-4706         |

#### HOSPITAL EMERGENCY NUMBERS

|   |            |
|---|------------|
| 1. Oakwood Hospital.....  | 336-3000   |
| 2. Outer Drive Hospital.....  | 386-2000   |
| 3. University of Michigan Hospital - Ann Arbor.....<br>(Poison Information) | 1-764-5120 |

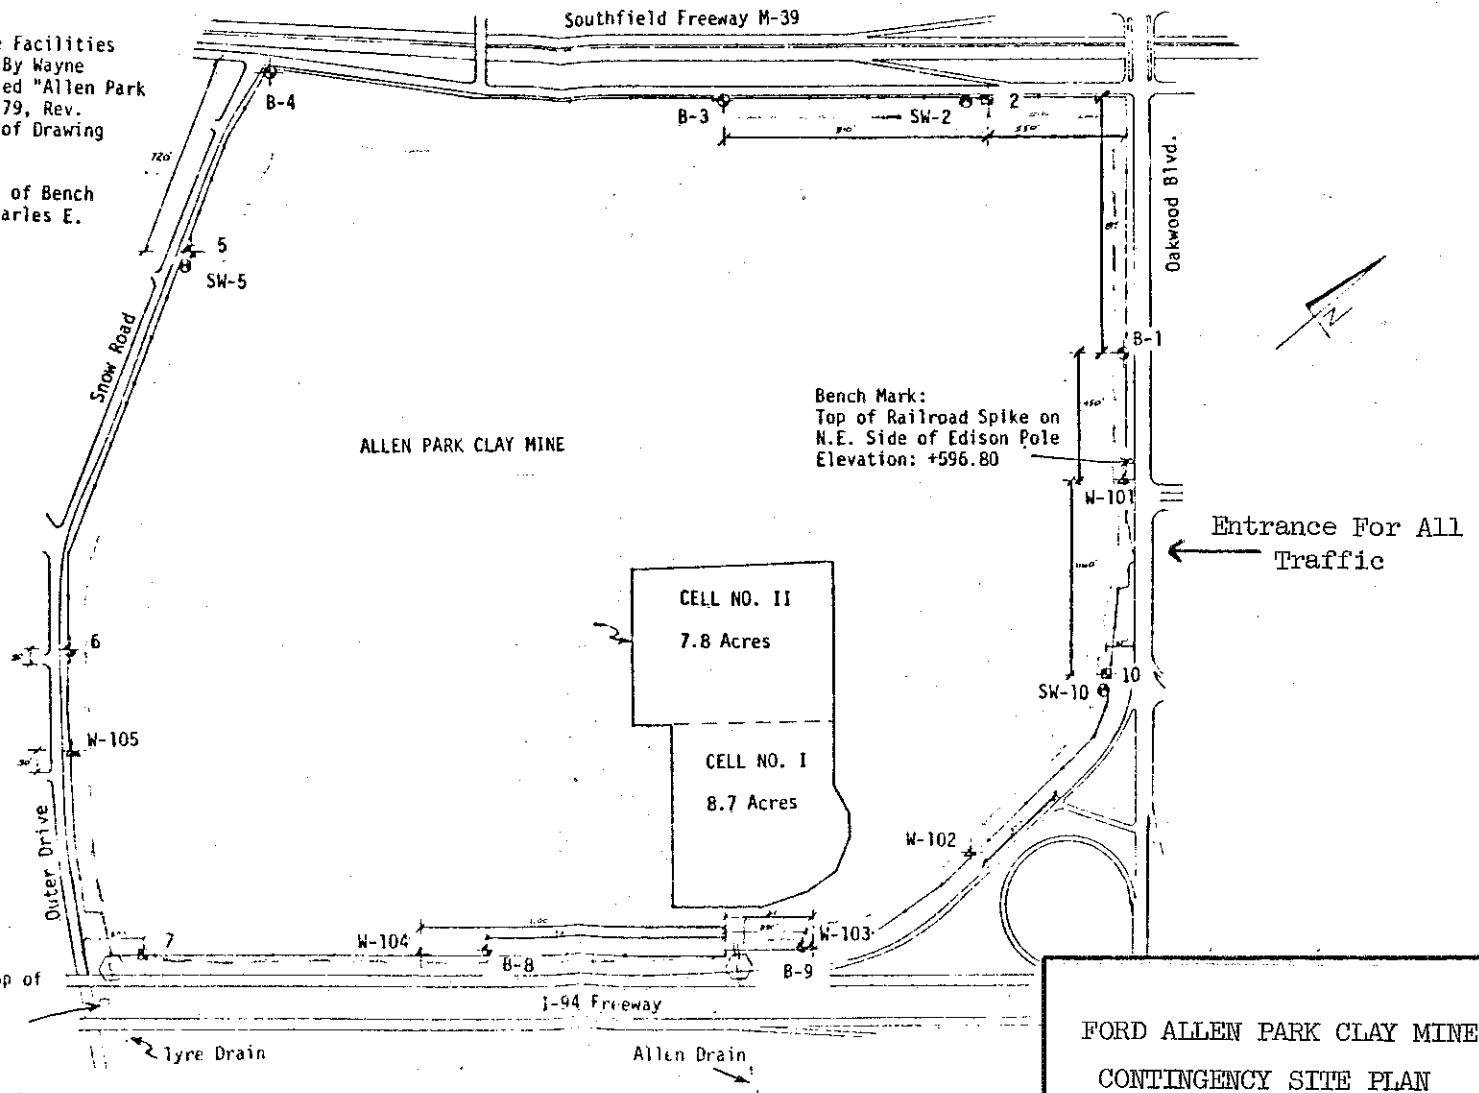

The person reporting the situation to the emergency coordinator should give the following information:

1. All circumstances known to exist which may effect emergency actions to be taken.
2. Name of person reporting conditions.
3. Location of problem area within the facility.
4. Time of the incident occurring, if known.
5. Type of materials involved, if known.
6. Any injuries to personnel or damage to equipment if such has occurred.
7. All actions taken, so far, to prevent further harm to human health or the environment.
8. How incident occurred, if known.
9. Request time of arrival for Emergency Coordinator at incident site and any further instructions for actions in the interim.

NOTES:

1. General Layout Of Site Facilities From Drawing Supplied By Wayne Disposal, Inc., Entitled "Allen Park Clay Mine" Dated 9-12-79, Rev. 5-1-81, Sheet No. C-2 of Drawing No. 79P - 23.6.
2. Location And Elevation of Bench Marks Obtained From Charles E. Raines Company

FORD ALLEN PARK CLAY MINE  
CONTINGENCY SITE PLAN

G-4b Identification of Hazardous Materials 40 CFR 264.56(b)

The emergency coordinator will immediately identify the character, source, extent of the release. The initial identification method will be to utilize visual analysis of the material and location of the release. Any wastes known or suspected to be involved in a release must be sampled (bottles available in manifest trailer).

G-4c-h

Upon receiving a call from facility personnel that an emergency condition exists, the emergency coordinator shall evaluate steps to be taken from the information reported and give instructions as required. The coordinator should then immediately proceed to the site, to conduct the following:

1. Assess extent of emergency.
2. Contact appropriate emergency support agencies if needed.
3. Take precautions to prevent spreading of a spill or fire to other areas.
4. Remove non-employees, and non-essential employees from incident area, particularly during operating hours.
5. Assemble all personnel at trailer for instructions and personnel count.  
Direct personnel in responding to the incident, if appropriate, or wait for outside emergency personnel and assist in their containment efforts.
6. Prevent additional traffic from entering incident area.
7. Clear road(s) for emergency vehicles and equipment.
8. Contact "hazardous waste checker" if on duty, or check waste inventory log for information on wastes in the incident area to determine potential hazards such as toxic, irritating or asphyxiating gases generated as a result of fire or explosion.
9. In event of fire, consider smoke visibility hazard on I-94 or Southfield Freeways and advise State Police personnel for action.

10. If an evacuation of personnel is appropriate, contact the National Response Center (800-424-8802) and report the following:
  - A. Name and phone number of reporter
  - B. Name and address of facility
  - C. Time and type of incident
  - D. Name and quantity of material involved, to the extent known
  - E. The extent of injuries if any
  - F. Possible hazards to human health, or the environment, outside the facility
11. Immediately after an incident, make assessment to determine the need for disposing of recovered waste, contaminated soil or surface waters or any other material that results from release, fire, or explosion at the facility. (Assume materials are hazardous)
12. The emergency coordinator must ensure that, in the affected area(s) of the facility:
  - a. No waste that may be incompatible with the released materials is treated, stored, or disposed of until cleanup procedures are completed.
  - b. All emergency equipment listed in the contingency plan is cleaned and fit for its intended use before operations are resumed.
13. The owner and operator must notify the Regional Administrator, and appropriate State and local authorities, that the facility is in compliance with applicable requirements before operations are resumed in the affected area(s) of the facility.

4c through 4m not applicable.

G-4n Landfill Leakage 40 CFR 264.52

If liquid is detected in the leak detection system or lysimeter monitoring system, the liquid will be analysed for contamination according to each respective environmental monitoring program. If a statistically significant increase in the concentration of analysed parameters is detected, in accordance with the provisions of the monitoring programs, the following procedure shall be implemented whenever an immediate resampling confirms the statistically significant increase:

- a. Notify the Director immediately by calling the Chief of the Waste Management Division, the Waste Management Division District Supervisor, or Department of Natural Resources 24 hour emergency response telephone at 1-800-292-4780, and by providing followup notification to the Chief of Waste Management Division in writing within seven days.
- b. Begin immediate action to implement the current contingency plan.
- c. Within 30 days, determine the cause of contamination and whether failure has occurred in the liner system.
- d. Provide the Chief of the Waste Management Division or his designee, with weekly telephone updates and written reports every two weeks regarding the progress to date in determining the cause of contamination, and the results of all samples from environmental monitoring conducted by the licensee.

G-5 Emergency Equipment and Power Sources 40 CFR 264.52 (e)

|                       |   |
|-----------------------|---|
| Fire Extinguishers    | - 8 located throughout the wheel wash building  |
| Telephone             | - located at the wheel wash building  |
| Fire Hydrant          | - located north of entrance gate  |
| Electrical Power      | - outlets located in wheel wash building and air monitoring stations                    |
| Misc. Mobil Equipment | - available at the Ford Rouge Plant upon request (front endloaders, vacuum truck, etc.) |
| Shower                | - located in wheel wash building  |

G-7      Evacuation Procedures    40 CFR 264.52(f)

The facility is an open field whereby specific evacuation routes and emergency aisle space are not required. Personnel are instructed to proceed to the manifest trailer if it is necessary to abandon their work station.

G-8      Required Reports    40 CFR 264.56(j)

The owner or operator must note in the operating record the time, date, and details of any incident that requires implementing the contingency plan.

Within 15 days after the incident, he must submit a written report on the incident to the U. S. EPA Regional Administrator. The report must include:

- a. Name, address, and telephone number of the owner and operator.
- b. Name, address, and telephone number of the facility.
- c. Date, time, and type of incident (e.g. fire, explosion).
- d. Name and quantity of material(s) involved.
- e. The extent of injuries, if any.
- f. An assessment of actual or potential hazards to human health or the environment, where this is applicable.
- g. Estimated quantity and disposition of recovered material that resulted from the incident.

Allen Park, Michigan 48101

RE: Allen Park Clay Mine, 17250 Oakwood Boulevard, Allen Park, Mi. 481

Dear Gentlemen/Ms.

In response to Federal requirements under the Resource Conservation and Recovery Act of 1976, all storers, treaters and disposers of hazardous waste must prepare a "Contingency Plan" and emergency procedures for implementation under situations that endanger human health and the environment such as fires, explosions or releases (sudden or non-sudden) of waste into the environment.

It is a requirement that the hazardous waste facility provide copies of the plan to appropriate emergency support agencies and facilities. The hazardous wastes disposed of at the Allen Park Clay Mine are generated at the Ford Rouge Manufacturing Complex, in particular in steelmaking and coking operations. These wastes are not flammable, ignitable, reactive nor corrosive. They pose virtually no threat to human health upon exposure.

Due to the small quantities and nature of these wastes, we believe the possibility of an emergency occurrence to be extremely remote; however, as the law requires we are supplying you with a copy of our plan. If any questions should arise, do not hesitate to call Walt Tomyn or me at 326-0200.

Very truly yours,  
Wayne Disposal, Inc.

*Mark A. Young*

RE: Allen Park Clay Mine

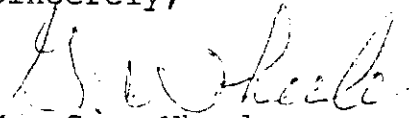

Dear Mr. Young:

In regards to your conversation with Mr. Greg Wheeler, Assistant Plant Engineer on November 23, 1981, we are requesting a chemical analysis breakdown of the hazardous material that is disposed of at the Allen Park Clay Mine.

This is to insure that should an accident occur that we at Outer Drive Hospital would have on file a statement as to the contents of the hazardous material for the protection of a possible emergency room case.

Thanking you in advance.

Sincerely,

  
Mr. Greg Wheeler,  
Assistant Plant Engineer

RICHARD A. HUEBLER  
CITY ADMINISTRATOR

## City of Allen Park

OFFICE OF ADMINISTRATOR  
16850 SOUTHFIELD ROAD  
ALLEN PARK, MICHIGAN 48101  
PHONE: 928-1400

June 17, 1987

Mr. Douglas A. Painter, Manager  
Ford Motor Company Mining Department  
3001 Miller Road  
Dearborn, Michigan 48121

Re: "Contingency (Emergency) Plan"  
Ford Motor Mine

Dear Mr. Painter:

I wish to thank you for your plan. It will become part of the City Plan for Emergency Management.

For your information:

Emergency Management Coordinator is  
Richard A. Huebler (City Administrator)  
16850 Southfield Road, Allen Park, MI 48101  
Phone: 928-1400

Deputy Emergency Management Coordinator is  
Carson C. Smith (Administrative Assistant)  
Address and phone number above

Environmental Inspector  
Ardys Bennett (Building Inspector)  
Address and phone number above

Hazardous Material Response  
Raymond Bertoncelli (Fire Chief)  
6730 Roosevelt, Allen Park, MI 48101  
Phone: 928-0024

Copies of your plan have been issued to the concerned parties.

Respectfully,

*Richard A. Huebler*

Richard A. Huebler  
City Administrator

Job Descriptions  
H-1a Job Titles/Job Descriptions 40 CFR 264.14(d)(1)

Hazardous Waste Shipment and Manifest Checker - Requisite qualifications are good judgement, common sense and good communication skills.

1. Inspection of hazardous waste shipments.
  - a. Identify hazardous wastes visually by comparison with on-site sample (visual and/or smell).
  - b. Verify volume of shipment visually with no more than 10% error (volume basis).
2. Direct transporter to dump hazardous wastes in designated area.
3. Sign valid manifests and retain necessary copies.
4. Record shipment information with disposal location cross-reference.
5. Deliver transporter to dump hazardous wastes in designated area.
6. When manifest discrepancies occur:
  - a. Contact generator for explanation.
  - b. Refuse permission to dispose of shipment if explanation in a. is not sufficient.
7. Keep disposal map locator up to date.
8. Make required inspections under the general inspection procedure.
9. Review aspects of facility inspections.
10. Activate when conditions warrant the Spill and Accident Prevention Plan, Contingency Plan and Emergency Procedures.

Operating Engineer - Requisite qualifications are good judgement, common sense, experience on heavy machinery operation and maintenance.

1. Maintain equipment (Tracked Dozer) in good working order.
2. Notify management of equipment problems.
3. Keep fill site graded and covered with inert material as conditions warrant.
4. Maintain area in neat and orderly appearance.
5. Assist manifest checker in observations required by the general inspection procedure.
6. Verify identity and volume of waste before burial.
7. Implement safety procedures.
8. Implement procedures for using, inspecting, repairing and replacing emergency and safety equipment.

Foreman - Requisite qualifications are good judgement and common sense, experience on heavy machinery operation and maintenance.

1. Responsible for day-to-day supervision of construction and maintenance personnel.
2. Make required site inspections.
3. Knowledge of the Spill and Accident Prevention Plan, Contingency Plan and Emergency Procedures.
4. Knowledge and implementation of safety procedures.
5. Functions as emergency coordinator in absence of Ford Motor Company officials.

Inspectors Responsibility - Requires good judgement, common sense and good communication skills.

1. Perform inspections as needed, in addition to a daily and weekly schedule.
2. Maintain the leachate sampling device. Maintain the leachate collection system.
3. Report to Ford representatives the status of facility operations.
4. Provide corrdination for facility activities.
5. Knowledge of the Spill and Accident Prevention Plan, Contingency Plan and Emergency Procedures.

Ford Training Program

Employees will be assembled every 12 months to review pertinent aspects of their job.

Hazardous Waste Shipment and Manifest Checker - Receives introductory on-the-job training.

1. Physical properties and characteristics of the wastes are discussed in detail.
2. Inspection and waste verification procedures are practiced in order to verify waste identity and volume.
3. Processing the manifest form is discussed including manifest discrepancies.
4. Recordkeeping procedures are discussed.
5. General inspection procedures are discussed.
6. Pertinent waste handling and disposal regulations are discussed.
7. The Spill and Accident Prevention Plan, Contingency Plan and Emergency Procedures are discussed.
8. Safety procedures are discussed.

Operating Engineer - Receives introductory on-the-job training.

1. Physical properties and characteristics of the wastes are discussed in detail.
2. Inspection and waste verification procedures are discussed in order to verify waste identity.
3. General inspection items and procedures are discussed.
4. Pertinent waste handling and disposal regulations are discussed.
5. The Spill and Accident Prevention Plan, Contingency Plan and Emergency Procedures are discussed.
6. Fill and grading plan are discussed.
7. Safety procedures and procedures for using, inspecting, repairing and replacing emergency safety and monitoring equipment are discussed.

Foreman - Receives introductory on-the-job training.

1. Physical properties and characteristics of the wastes are discussed in detail.
2. Processing the manifest form is discussed including manifest discrepancies.
3. General inspection procedures are discussed and practiced.
4. Pertinent waste handling and disposal regulations are discussed.
5. The Spill Plan and Accident Prevention Plan, Contingency Plan and Emergency Procedures are discussed.
6. Safety procedures and procedures for using inspecting, repairing and replacing emergency, safety and monitoring are discussed.
7. Fill and grade plans are discussed.

Inspectors Responsibility - Requires good judgement, common sense and good communication skills.

1. Perform inspections as needed, in addition to a daily and weekly schedule.
2. Maintain the leachate sampling device. Maintain the leachate collection system.
3. Report to Ford representatives the status of facility operations.
4. Provide coordination for facility activities.
5. Knowledge of the Spill and Accident Prevention Plan, Contingency Plan and Emergency Procedures.

Michigan Hazardous Waste Industry  
Training and Technical Assistance Program

An example of the training provided by the independent waste management concerns is provided as Attachment 20.

A recorded schedule of trained employees is provided as Attachment 21.

## HAZARDOUS WASTE HANDLER'S TRAINING COURSES

### Michigan Hazardous Waste Industry Training and Technical Assistance Program

Michigan State University, Community Development Programs  
27 Kellogg Center  
East Lansing, MI 48824

In cooperation with the Liquid Industrial Control Association

Supported by a grant from the Michigan Department of Labor  
Safety Education and Training Program

Michigan Hazardous  
Waste Industry  
Training and Technical  
Assistance Program

Community  
Development

Birmingham, MI 48011  
(313) 642-9797

April 13, 1983

To: Members, Act 64 Advisory Committee

From: Lynn A. Corson, Ph.D. *LAC*

Subject: Conveyance of Material Re: Michigan Hazardous Waste  
Industry Training and Technical Assistance Program

It is with pleasure that I respond to the request of one of your members, Mr. Walter Pociask, K & D Industrial Services, and provide the attached information.

The Curriculum Guide provides a general outline of the various courses offered to employees of firms licensed as processors or haulers of hazardous waste under Act 64 and transporters of liquid industrial waste licensed under Act 136.

The brochure describes the training and technical assistance program in more detail.

I will be pleased to answer any questions that the Committee or its individual members may have regarding the program.

## 005 Overview: Safety Hazards of Working with Hazardous Wastes Instructional Outline

### Topics

1. Physical Properties of Chemicals
  - a. Physical states: solid, liquid, gas, vapor.
  - b. Organics and inorganics - solvents, etc.
  - c. Acids and bases - pH
2. Incompatible chemicals - problems with mixing
  - a. Release of noxious gases: e.g., cyanide,  $H_2S$
  - b. Release of heat - concentrated acids and bases
  - c. Other examples - MDOL/SET list
3. Storage and labeling - applies to all containers - large or small
  - a. Proper identification of contents - keep in original container whenever possible
  - b. Store in proper area: e.g., flammables, incompatibles, corrosives
  - c. Other considerations - don't stack too high to present handling difficulty; leakage problems; aisles between; containment provisions
4. Materials handling -
  - a. Housekeeping
  - b. Proper lifting techniques
  - c. Drum handling
  - d. Lift trucks
  - e. MDOL/SET "5 minute safety talks"
5. Controls - Engineering controls and Personal Protective Equipment
  - a. Hazards Recognition
    - 1) Falling
    - 2) Striking
    - 3) Being caught
    - 4) Contact injuries
    - 5) Breathing in harmful atmospheres
  - b. Other - machine guarding, blind corners, barricade, construction
6. Fire Safety
  - a. Prevention - housekeeping; call list; disaster plan
  - b. Theory - fire triangle; flash point; L.E.L.; U.E.L.; extinguishment principles
  - c. Equipment - blanket; extinguisher use -  $CO$ ,  $CO_2$ , dry chemical
7. Confined Space Entry - Definition
  - a. Legal - MIOSHA rules
  - b. Hazards awareness -  $CO$ ,  $CO_2$ , toxic gases, flammables
  - c. Atmosphere testing -  $\%O_2$  and L.E.L.; meters; toxic gas sampling; ventilation area
  - d. Victim rescue and equipment for safe entry
8. First Aid - Immediate action -
  - a. Prevention and Readiness - first aid rules and kits
  - b. Procedures - immediate flushing, call list
  - c. Equipment - drenching showers, eye washes
  - d. Chronic - dermatitis prevention

### Resources

1. Handout - Employee Safe Work Manual - Dray Publishing Co.
2. Chart - Flammable liquid chart

## Physical States of Matter

Matter can exist in three different states, designated as solid, liquid, and gas (Fig. 1-1), which can be distinguished by certain qualities.

Fig. 1-1 The physical states of matter as illustrated by water.

A good example of these three states of matter is furnished by a block of ice. As ice it is a solid, the shape of which can be changed by moderate force, but its volume can be changed only by a very great force; i.e., ice is only very slightly compressible. If its temperature is raised it melts, that is, it passes into the liquid state as water. Its shape then will depend on the vessel it is in, or if spilled on the ground it will flow into whatever cavities and spaces there are between the particles that make up the soil. As water, its volume can be changed very little because, like ice, it is nearly incompressible. Heated to boiling in an open vessel, it changes to a gas or vapor and will expand and disappear completely in the air. Heated in a closed vessel, the vapor is retained in the form of steam, causing pressure on the sides of the vessel.

This expansion due to the change from the liquid to the gaseous state by heating is extremely important. Without it there would be no steam engines or steam power plants. This has its bad side too, for it causes boiler explosions and furnishes most of the explosive force of volcanoes.

Few substances can change as readily under normal conditions into the three states of matter as water. But the safety man should recognize that change in the state of matter, as from solid to liquid to gaseous, occurs in many chemical processes. The degree of expansion when changing from one state to another (liquid to gas) has marked safety implications.

### Vapor

The term vapor is applied to the gaseous form of substances that at ordinary temperature can exist both as a gas and as either a liquid or a solid. For example, gasoline, normally a liquid, vaporizes to produce a gas which when mixed with the correct amount of air makes our automobiles run. Water at all ordinary temperatures evaporates to form a gas which we ordinarily refer to as water vapor. Vapors are often a nuisance, a byproduct of the use of the liquid or solid producing them. They are also used to do work, such as vapor degreasing. Many vapors are toxic, for example, the vapor of carbon tetrachloride; and the safety man should be on guard whenever vapors are encountered.

### Dust

For all practical purposes we can define dusts as particles of solid matter divided by abrasion and fine enough to float along and to be distributed by ordinary air motion. This, of course, means bad air for breathing and if the dust is combustible a fire and explosion hazard as well.

### Fume

Fumes are particles of solid matter also, but the term fume is correct only for particles formed when vapors are condensed from heating metals or other substances.

### Mist

Mists are droplets of liquid so fine that they float in the air. They may be formed by condensation from the gaseous form (example, fog above a pond on a still cold morning), by gas escaping from a liquid and carrying fine droplets with it (example, chromium plating tank), or by breaking a liquid up into a very fine spray (example, air brushing).

## Chemical and Physical Changes

When carbon, a black solid substance, burns in air, an invisible gas consisting of both carbon and oxygen (carbon dioxide) is formed. When milk sours, the sugar in the milk is converted into an acid, and the composition and the properties of the acid differ greatly from those of the sugar. Iron rust formed by the corrosion of iron metal contains oxygen as well as iron, and it is therefore a different substance with different properties. All such changes are called chemical changes. A chemical change always produces at least one substance entirely different in composition and properties from those that existed before the change occurred. In addition, all chemical changes are accompanied by either the formation or absorption of some form of energy.

Changes that do not alter the composition of a substance are known as physical changes. The melting of ice, the freezing of water, the conversion of water to steam, the condensation of steam to water, the dissolving of sugar in water, and the heating of iron to redness, are all examples of physical change. In each of these there is a change in properties but there is no alteration of the chemical composition of the substances involved. Water, whether in the solid, liquid, or gaseous state, retains the same chemical composition. Sugar is the same chemical substance in solution in water as it is in the solid state and can readily be recovered as crystals by evaporation of the water. Iron, an emitter of light when red hot, is still the same substance that reflects light when cold.

## Skin Absorption

The intact skin (see Fig. 17-1) is an excellent barrier to passage of most chemicals, especially against most water solutions. However, many chemicals will be absorbed through the skin, while others, which will not be absorbed through the intact skin, may enter the body through cuts, blisters, or wounds. Absorption this way may be more dangerous than through the respiratory or digestive system, which may provide defensive mechanisms, since it is absorbed directly into the bloodstream. Chemicals that will be absorbed even through an intact skin include tetraethyl lead, used as a knock suppressant in high-octane gasoline, aniline, hydrazine, the boranes, and nitroglycerine.

## Corrosives

Corrosives damage by chemical reaction with the skin they contact. In addition to injuring the skin and the underlying tissues, the wound provides a point of entry for the toxicant to reach the bloodstream, producing an effect worse than skin damage.

Corrosive burns can be caused by strong acids or alkalis. Alkalis can cause progressive burns, the injury increasing as the alkali moves through damaged tissue. This is especially critical in injuries to the eye, where delicate tissues can be damaged little by little until vision is destroyed. If a corrosive chemical is swallowed, it will cause pain in the mouth, throat, and stomach. There will usually be vomiting, difficulty in swallowing and breathing, distension and pain caused by gas in the stomach.

Some common corrosives are concentrated acids, such as nitric, hydrochloric, sulfuric, and oxalic; strong alkalis, such as sodium or potassium hydroxide; and reactive elements, such as iodine, chlorine, or fluorine.

The severity of a corrosive burn depends on the concentration and type of corrosive chemical, whether the contact was covered or uncovered, and the length of time of contact. For this reason, a harmful agent should be washed away as soon as possible and neutralized with a mild antidote if one is available.

A covered skin contact usually creates a severer skin reaction than one which is uncovered. Tricresyl phosphate evaporates rapidly from an uncovered skin, with a sensation of coldness and a brief mild redness. Clothing wet with tricresyl phosphate produces a burning sensation and blisters like those of a second-degree burn. Even less harmful liquids, such as gasoline, will produce similar reactions. The importance of prompt removal of contaminated clothing and of damaging chemicals is apparent.

## Dermatitis

Dermatitis is skin inflammation caused by defatting of the skin or by contact with an irritating or sensitizing substance. Exposure to solvents often causes removal of the oils that keep the skin soft and pliable, making it dry, scaly, somewhat thickened, and with a tendency to crack easily. Some redness may result from the irritating effects created by the absence of fats. Such skins often have poor resistance to bacterial infection and heal slowly when injured. Replacement of oils with creams and lotions to control the condition is only partly effective. The only hope of recovery is generally removal from further

## Damage

Of all skin contacts, those with the eyes are the most damaging, because of their sensitivity. Most materials have the ability to injure the eye to some degree. Solids can harm by abrasion or by chemical action. The mildest injury is probably irritation which causes redness, watering, and stinging. More severe irritation can damage the cornea, the transparent covering of the eye, involving a dry scratching feeling and various levels of pain.

A corneal burn is the commonest chemical eye injury. Corrosive vapors or fine spray can cause many tiny burn spots. Contact with a strong mineral acid or alkali can damage or destroy vision. The tendency of alkali burns to spread, even though emergency treatment has been given, makes them particularly troublesome.

A hazard that has developed in the past few years is the possibility that a sprayed or splashed corrosive material, either vapor or fine liquid, may be caught between a contact lens and the eye. This keeps the chemical in close contact with the eye for an abnormally long period, aggravating the burn.

## Solvents

The solvents we are interested in are those that are hazardous. Some give off vapors that will burn and explode; for example, gasoline, naphtha, benzene, methanol (wood alcohol). Some are extremely toxic and their vapors, if breathed, can poison one; examples, benzene, carbon tetrachloride, methanol. Note that benzene and methanol present both hazards.

Carbon tetrachloride formerly was used in fire extinguishers. Its high toxicity, however, makes it unsafe in many situations, and many authorities now prohibit its further use as a fire extinguishing agent.

Another point to remember is that the higher the temperature the faster the vapors come off from the liquid. So if the process in which the solvent is used heats it up, the hazard is increased. The amount (concentration of vapor in the air) reaches the point at which it can burn or explode, or at which it can poison one more quickly than if it were not heated. That might make it seem that the hazard is greater in hot weather than cold, but this may be offset by the fact that windows and doors are likely to be kept open in summer and kept tightly closed in winter, at least wherever winters are cold.

Chemical Symbols

The chemical symbols are so universally used to indicate the chemical compounds that every safety man should know the symbols of at least the common elements. These symbols make possible a simple means of indicating the makeup (chemical formula) of each compound. For example, the formula for carbon monoxide is CO, which shows that each molecule of carbon monoxide is made up of one atom each of carbon and oxygen. Where there is more than one atom of an element in a compound a subscript is used to show it. For example, carbon dioxide is CO<sub>2</sub>, meaning that one carbon and two oxygen atoms have combined. Water is H<sub>2</sub>O. By adding another atom of oxygen to H<sub>2</sub>O we get hydrogen peroxide H<sub>2</sub>O<sub>2</sub>, a mild solution which has long been used by women to change their brown tresses to blond. When concentrated it is a dangerously corrosive chemical. What a difference that extra little atom of oxygen makes!

We need not concern ourselves with the highly complex compounds of organic chemistry. Even the chemist uses the name if the formula is long. If it has a short trade name he will probably use that. For example, the formula for the widely used insecticide DDT is (C<sub>14</sub>H<sub>9</sub>Cl<sub>3</sub>), CHCl<sub>3</sub>. Its chemical name is dichloro-diphenyl-trichloroethane. No one will ever expect anyone but a chemist to know its chemical name let alone its chemical formula. But a safety man should recognize the formula, as well as the name, for many of the chemical compounds he will encounter. Here are a few to start with.

| Inorganic Compounds                          | Organic Compounds  |
|--|--|
| Sulfuric acid—H <sub>2</sub> SO <sub>4</sub> | Carbon tetrachloride—CCl <sub>4</sub>                          |
| Nitric acid—HNO <sub>3</sub>                 | Ethyl alcohol (grain alcohol)—C <sub>2</sub> H <sub>5</sub> OH |
| Hydrochloric acid—HCl                        | Benzene (benzol)—C <sub>6</sub> H <sub>6</sub>                 |
| Ammonia—NH <sub>3</sub>                      | Toluene—CH <sub>3</sub> C <sub>6</sub> H <sub>5</sub>          |
| Caustic soda (lye)—NaOH                      | Methyl alcohol (methanol)—CH <sub>3</sub> OH                   |
| Caustic potash—KOH                           |  |

Acids, Bases, and Salts

**A.** Acids are compounds that have one or more atoms of loosely held hydrogen. This hydrogen acts as though it were dissatisfied with its partner and is always looking for one it likes better, for example, hydrochloric acid (HCl). The hydrogen atom is so dissatisfied that it will take up with almost anything. Of course, the other partner, chlorine, is not too happy either. For example, when a molecule of HCl meets up with a molecule of ordinary lye (NaOH), they swap partners fast and get hot in doing so. The reaction is HCl + NaOH = NaCl + H<sub>2</sub>O + heat. The reaction goes fast and is likely to form steam and cause spattering or explosion.

Three acids are found in every laboratory and many plants, and are so essential that they have been referred to as the workhorses of the chemical industry. They are made and used in amounts of millions of tons per year. These acids are hydrochloric (HCl), sulfuric (H<sub>2</sub>SO<sub>4</sub>), and nitric (HNO<sub>3</sub>). Because of their dissatisfied hydrogen element, they are very active chemically, they attack a very wide variety of substances including human skin and flesh and eyes. They are not flammable, that is they do not burn or explode. There is, however, the ever present possibility of leakage or spillage into materials or substances with which they can react to cause fire or explosion or liberate toxic vapors or gases. Nitric acid in particular is likely to set fire to sawdust, shavings, straw, and many other finely divided combustible materials. Both hydrochloric and nitric acids give off gas when heated and, therefore, can burst their containers. The vapors given off by nitric acid when it is heated are very dangerous when breathed in any considerable amount, they are likely to cause fatal lung damage. The vapors of HCl and H<sub>2</sub>SO<sub>4</sub> are so intensely irritating that they are unbreathable. This property is a safeguard because it gives warning of even very low concentration in the air of the workroom. One gets out quickly, if he can, to get his breath and get the sting out of his eyes. If the concentration is high and he can't get out, he dies.

Acids should be stored in cool places away from the sun and away from other chemicals and waste materials. The possibility leakage to floors below (if any) should always be taken into account. Where amounts kept are considerable, floors should be impervious, acid resisting material, and arranged to be hosed down as needed.

Provisions should be made for the safe handling of containers, particularly carboys. Various types of carboy handling equipment (lifters, carriers) are available commercially.

Protective clothing—rubber aprons, gloves, and perhaps acid resisting shoes—should be worn when handling acids. Chemical goggles or face shields should always be worn when handling or using acids of any kind.

**NOTE.** Bulletin 267, "The Inorganic Acids," of the U.S. Department of Labor Bureau of Labor Standards, contains detailed information on the potential hazards connected with the use and handling of acids and recommended procedures for control measures.

**Bases.** Bases are compounds that have one or more "hydroxyl groups. A hydroxyl group is an atom of oxygen linked to an atom of hydrogen (OH). Chemically, it acts much as though it were a single atom.

We have two very active bases that are widely used: caustic soda (sodium hydroxide) (NaOH) and caustic potash (potassium hydroxide) (KOH). Their hazards are similar and we treat them alike. They are called "caustics" because they eat most organic substances: skin, fat, flesh, hair, your shoes, the wooden floor. They react with fats to form soap and glycerine. Ordinary lye is NaOH dissolved in water.

These two caustics are marketed and handled in the form of lump pellets, sticks, and in cans or drums of light gage sheet steel. Molten caustic is poured into a drum. It hardens on cooling to a white solid mass. The user strips the sheet metal off and chops or breaks up the caustic into pieces of convenient size. This involves the hazard of flying chips that will stick to sweaty skin and burn. Caustics can cause very serious eye damage. Suitable protective equipment—aprons, gloves, goggles or face shields—must be worn when handling or using caustics. Also, safety should be provided for other nearby workmen.

Calcium (Ca) gives us another widely used base that, while not as caustic as caustic potash or caustic soda, offers hazards. Ordinary limestone is calcium carbonate (CaCO<sub>3</sub>). When burned in a kiln it gives off CO<sub>2</sub> and becomes quicklime (CaO). If water is added to CaO it swells up, gets hot, and becomes Ca(OH)<sub>2</sub> (caustic lime), that is, CaO + H<sub>2</sub>O = Ca(OH)<sub>2</sub>. It will then take CO<sub>2</sub> out of the air, turn the H<sub>2</sub>O loose and again becomes CaCO<sub>3</sub>. This is the reaction by which lime plaster and lime mortar harden.

CaO and Ca(OH)<sub>2</sub> are both caustic but are much less so than NaOH and KOH. The fact that quicklime heats up on wetting has caused many fires, particularly in building supply yards. Quicklime dumped into a wooden bin, the roof leaks, fire starts in the bin; the fire is carried to the nearby lumber. Another lumber yard goes up in flames. Such fires are spectacular and very expensive, all because of failure to store quicklime properly. Quicklime should be stored in concrete bins with leak-proof metal covers, preferably hinged so that they won't be left off or thrown back. Then make doubly sure by having a good roof.

**Salts.** A salt is a compound, other than water, which is formed by the reaction of an acid with a base. Salts are mostly stable, even when heated, compounds well satisfied with their lot in life. Some of them, however (the offspring of the "per" acids, perchloric, for example), are very touchy and blow up on very slight provocation. The salts of nitric acid (nitrates) are for the most part fairly stable but if heated with oxygen-hungry substances they may give up the oxygen and set their nitrogen free without much fuss, or they may start a fire or give off poisonous gases or both. So don't fool with nitrates unless you know them. The same is true of perchlorates and the like, only more so.

## B. DOT HAZARD CLASS

Enter the two digit code from the table below which corresponds to the DOT hazard class of the waste described. If the waste described has been shipped under more than one DOT hazard class, use a separate line for each DOT hazard class.

| DOT HAZARD CLASS       | Code |
|------------------------|------|
| Combustible .....      | .01  |
| Corrosive .....        | .02  |
| Etiologic agent .....  | .03  |
| Explosive A .....      | .04  |
| Explosive B .....      | .05  |
| Explosive C .....      | .06  |
| Flammable gas .....    | .07  |
| Flammable liquid ..... | .08  |
| Flammable solid .....  | .09  |
| Irritating agent ..... | .10  |
| Nonflammable gas ..... | .11  |
| Organic peroxide ..... | .12  |
| ORM-A .....            | .13  |
| ORM-B .....            | .14  |
| ORM-E .....            | .15  |
| Oxidizer .....         | .16  |
| Poison A .....         | .17  |
| Poison B .....         | .18  |
| Radioactive .....      | .19  |

*DEGREE OF HAZARD*

## C. EPA HAZARDOUS WASTE NUMBER

For listed wastes, enter the four digit EPA Hazardous Waste Number from 40 CFR Part 261, Subpart D (see Appendix) which identifies the waste. For unlisted wastes which exhibit hazardous characteristics, enter the four digit EPA Hazardous Waste Number from 40 CFR Part 261, Subpart C (see Appendix) which is applicable to the waste.

For a mixture of more than one listed or unlisted waste, enter all of the relevant EPA Hazardous Waste Numbers. Four spaces are provided for this on each waste line. If more space is needed, continue on the next line(s), and leave all other items on that line blank, as shown by the example below. Generators who ship lab packs are currently required to list the hazardous waste number for each of the constituents of the pack.

**3.2 Waste Characteristics.** The hazardous substance that was observed for scoring the release category may be different from the substance used to score waste characteristics.

**Reactivity and incompatibility.** measures of the potential for sudden releases of concentrated air pollutants, are evaluated independently, and the highest value for either is recorded on the work sheet.

**Reactivity** provides a measure of the fire/explosion threat at a facility. Assign a value based on the reactivity classification used by NFPA (see Table 11). Reactivity ratings for a number of common compounds are given in Table 4.

TABLE 11.—NFPA REACTIVITY RATINGS

| NFPA level   | Assigned value |
|--|----------------|
| 0 Materials which are normally stable even under fire exposure conditions and which are not reactive with water.   | 0              |
| 1 Materials which in themselves are normally stable but which may become unstable at elevated temperatures and pressures or which may react with water with some release of energy but not violently.  | 1              |
| 2 Materials which in themselves are normally unstable and readily undergo violent chemical change but do not detonate. Includes materials which can undergo chemical change with rapid release of energy at normal temperatures and pressures or which can undergo violent chemical change at elevated temperatures and pressures. Also includes those materials which may react violently with water or which may form potentially explosive mixtures with water. | 2              |
| 3 Materials which in themselves are capable of detonation or of explosive decomposition or of explosive reaction but which require a strong initiating source or which must be heated under confinement before initiation. Includes materials which are sensitive to thermal or mechanical shock at elevated temperatures and pressures or which react explosively with water without requiring heat or confinement.   | 3              |
| 4 Materials which in themselves are readily capable of detonation or of explosive decomposition or explosive reaction at normal temperatures and pressures. Includes materials which are sensitive to mechanical or localized thermal shock.   | 4              |

TABLE 12.—INCOMPATIBLE MATERIALS

In the lists below, the mixing of a Group A material with a Group B material may have the potential consequence as noted.

| Group 1-A  | Group 1-B                                  |
|--|--|
| Acetylene sludge   | Acid sludge.                               |
| Alkaline caustic liquids                                   | Acid and water.                            |
| Alkaline cleaners  | Battery acid.                              |
| Alkaline corrosive liquids                                 | Chemical cleaners.                         |
| Alkaline corrosive battery                                 | Electrolytic acid.                         |
| Radiation  |  |
| Caustic wastewater   | Etching acid liquid or solvent.            |
| Line sludge and other corrosive sludges.                   | Pickling liquor and other corrosive acids. |
| Line wastewater  | Spent acid.                                |
| Line and water   | Spent mixed acid.                          |
| Spent caustic  | Spent sulfuric acid.                       |
| Potential consequences: Heat generation, violent reaction. |  |
| Group 2-A  | Group 2-B                                  |
| Aluminum   | Any waste in Group 1-A or 1-B.             |
| Borofluor  |  |
| Calcium  |  |
| Lithium  |  |
| Potassium  |  |

TABLE 12.—INCOMPATIBLE MATERIALS—Continued

In the lists below, the mixing of a Group A material with a Group B material may have the potential consequence as noted.

| Group 3-A   | Group 3-B  |
|---|--|
| Sodium  | Any concentrated waste in Groups 1-A or 1-B.   |
| Zinc powder   | Calcium.   |
| Other reactive metals and metal hydrides.   | Lithium.   |
| Potential consequences: Fire or explosion, generation of flammable hydrogen gas.      | Metal hydrides.  |
|   | Potassium.   |
|   | SO <sub>2</sub> Cl <sub>2</sub> , SOCl <sub>2</sub> , POCl <sub>3</sub> , OCl <sub>2</sub> , SOCl <sub>2</sub> . |
|   | Other water-reactive waste.  |
|   | Potential consequences: Fire, explosion, or heat generation, generation of flammable or toxic gases.             |
| Group 4-A   | Group 4-B  |
| Alcohols  | Concentrated Group 1-A or 1-B wastes.  |
| Aldehydes   | Group 2-A wastes.  |
| Halogenated hydrocarbons  |  |
| Nitrated hydrocarbons   |  |
| Unsaturated hydrocarbons  |  |
| Other reactive organic compounds and solvents.  |  |
| Potential consequences: Fire, explosion, or violent reaction.                         |  |
| Group 5-A   | Group 5-B  |
| Spent cyanide and sulfide solutions.  | Group 1-B wastes.  |
| Potential consequences: Generation of toxic hydrogen cyanide or hydrogen sulfide gas. |  |
| Group 6-A   | Group 6-B  |
| Chlorates   | Acetic acid and other organic acids.   |
| Chlorine  | Concentrated mineral acids.  |
| Chlorides   | Group 2-A wastes.  |
| Chromic acid  | Group 4-A wastes.  |
| Hypochlorites   | Other flammable and combustible wastes.  |
| Nitrates  |  |
| Nitric acid, fuming   |  |
| Perchlorates  |  |
| Permanganates   |  |
| Peroxides   |  |
| Other strong oxidizers  |  |
| Potential consequences: Fire, explosion, or violent reaction.                         |  |

Source: Hazardous Waste Management Law, Regulations, and Guidelines for the Handling of Hazardous Waste, California Department of Health, Sacramento, California, February 1975.

**Incompatibility** provides a measure of the increased hazard when hazardous substances are mixed under uncontrolled conditions, leading to production of heat, pressure, fire, explosion, violent reaction, toxic dusts, mists, fumes or gases, or flammable fumes or gases. Table 12 provides examples of incompatible combinations of materials.

## 7.0 Fire and Explosion

Compute a score for the fire and explosion hazard mode,  $S_{FE}$ , when either a state or local fire marshal has certified that the facility presents a significant fire or explosion threat to the public or to sensitive environments or there is a demonstrated fire and explosion threat based on field observations (e.g., combustible gas indicator readings). Document the threat.

**7.1 Containment.** Containment is an indicator of the measures that have been taken to minimize or prevent hazardous substances at the facility from catching fire or exploding. Normally it will be given a value of 3 on the work sheet (Figure 11). If no hazardous substances that are individually ignitable or explosive are present and those that may be hazardous in combination are segregated and isolated so that they cannot come together to form incompatible mixtures, assign this factor a value of 1.

**7.2 Waste Characteristics.** Direct evidence of ignitability or explosion potential may exist in the form of measurements with appropriate instruments. If so, assign this factor a value of 3; if not, assign a value of 1.

Additional information can be obtained from *A Method for Determining the Compatibility of Hazardous Wastes*, H. K. Halayama, et al., EPA-600/2-80-076 (1980). Assign a value using the following guidance:

| Incompatibility                        | Assigned value |
|--|----------------|
| No incompatible substances are present | 0              |
| Present but do not pose a hazard       | 1              |
| Present and may pose a future hazard   | 2              |
| Present and posing an immediate hazard | 3              |

**Toxicity** should be rated for the most toxic of the substances that can reasonably be expected to be transported away from the facility via the air route. Using the information given in Tables 4, 6, and 7, assign values as follows:

| Toxicity                          | Assigned value |
|-----------------------------------|----------------|
| Sax level 0 or NFPA level 0       | 0              |
| Sax level 1 or NFPA level 1       | 1              |
| Sax level 2 or NFPA level 2       | 2              |
| Sax level 3 or NFPA levels 3 or 4 | 3              |

## PARTIAL LIST OF INCOMPATIBLE CHEMICALS \*

Substances in the right-hand column should be stored and handled so they cannot possibly contact corresponding substances in the left-hand column.

|  |  |
|--|--|
| Alkaline and alkaline earth metals, such as sodium, potassium, cesium, lithium, magnesium, calcium, aluminum | Carbon dioxide, carbon tetrachloride, and other chlorinated hydrocarbons. (Also prohibit water, foam, and dry chemical on fires involving these metals.)         |
| Acetic acid  | Chromic acid, nitric acid, hydroxyl containing compound ethylene glycol, perchloric acid, peroxides, and permanga  |
| Acetone  | Concentrated nitric and sulfuric acid mixtures.  |
| Acetylene  | Chlorine, bromine, copper, silver, fluorine, and mercury.  |
| Ammonia (anhyd.)   | Mercury, chlorine, calcium hypochlorite, iodine, bromid and hydrogen flouride.   |
| Ammonium nitrate   | Acids, metal powders, flammable liquids, chlorates, nitri sulfur, finely divided organics or combustibles.   |
| Aniline  | Nitric acid, hydrogen peroxide.  |
| Bromine  | Ammonium, acetylene, butadiene, butane and other petroleum gases, sodium carbide, turpentine, benzene, and finely divided metals.                                |
| Calcium carbide  | Water (see also acetylene).  |
| Calcium oxide  | Water.   |
| Carbon, activated  | Calcium hypochlorite.  |
| Copper   | Acetylene, hydrogen peroxide.  |
| Chlorates  | Ammonium salts, acids, metal powders, sulfur, finely divided organics or combustibles.   |
| Chromic acid   | Acetic acid, naphthalene, camphor, glycerine, turpentine, alcohol, and other flammable liquids.  |
| Chlorine   | Ammonia, acetylene, butadiene, butane and other petrol gases, hydrogen, sodium carbide, turpentine, benzene, and finely divided metals.                          |
| Chlorine dioxide   | Ammonia, methane, phosphine, and hydrogen sulfide.   |
| Fluorine   | Isolate from everything.   |
| Hydrocyanic acid   | Nitric acid, alkalies.   |
| Hydrogen peroxide  | Copper, chromium, iron, most metals or their salts, any flammable liquid, combustible materials, aniline, nitro-methane, caustic soda and other strong alkalies. |
| Hydrofluoric acid, anhyd. (Hydrogen fluoride)  | Ammonia, aqueous or anhydrous.   |
| Hydrogen sulfide   | Fuming nitric acid, oxidizing gases.   |
| Hydrocarbons (benzene, butane, propane, gasoline, turpentine, etc.)  | Fluorine, chlorine, bromine, chromic acid, sodium peroxide.  |
| Iodine   | Acetylene, ammonia (anhyd. or aqueous).  |

**Mercury**

Acetylene, fulminic acid, ammonia.

nitric acid (conc.)

Acetic acid, aniline, chromic acid, hydrocyanic acid, hydrogen sulfide, flammable liquids, flammable gases, and nitritable substances.

Nitroparaffins

Inorganic bases.

Oxygen

Oils, grease, hydrogen, flammable liquids, solids or gases.

Oxalic acid

Silver, Mercury.

Perchloric acid

Acetic anhydride, bismuth and its alloys, alcohol, paper, wood, grease, oils.

Peroxides, organic

Acids (organic or mineral); avoid friction.

Phosphorus (white)

Air, oxygen.

Potassium Chlorate

Acids (see also chlorate).

Potassium perchlorates

Acids (see also perchloric acid).

Potassium permanganate

Glycerine, ethylene glycol, benzaldehyde, sulfuric acid,

Silver

Acetylene, oxalic acid, tartaric acid, ammonium compounds

Sodium

See alkaline metals (above).

sodium nitrate

Ammonium nitrate and other ammonium salts.

Sodium oxide

Water.

Sodium peroxide

Any oxidizable substance, such as ethanol, methanol, glacial acetic acid, acetic anhydride, benzaldehyde, carbon disulfide, glycerine, ethylene glycol, ethyl acetate, methyl acetate, and furfural.

Sulfuric acid

Chlorates, perchlorates, permanganates.

Zirconium

Prohibit water, carbon tetrachloride foam, and dry chemical on zirconium fires.

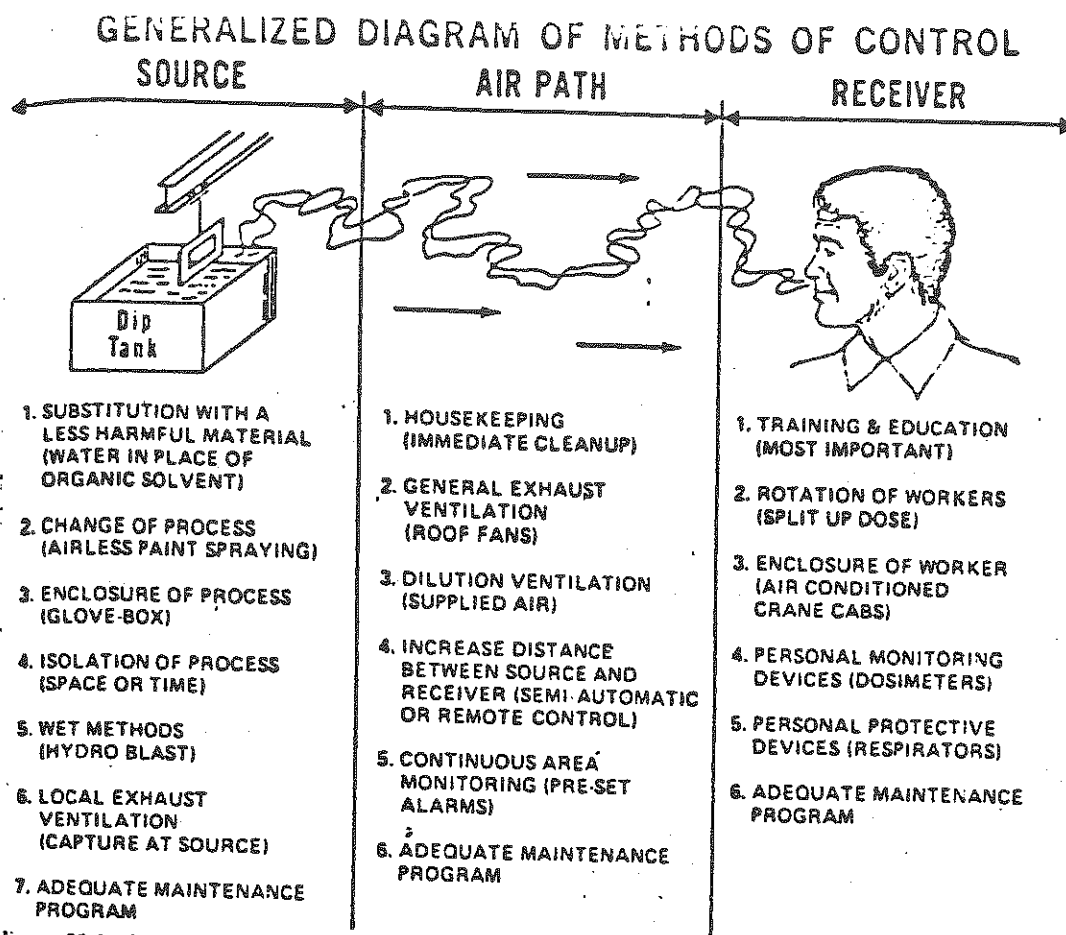

FIGURE 20-1.—To determine the extent of exposure, locate the contaminant source, the path it travels to the worker, and the employee's work pattern and use of protective equipment.

### Kinds of Protective Equipment

There are two broad categories of protective devices: protective clothing and respiratory protective equipment. Though there are far too many different kinds of items to cover them all in this handbook, a few things can be said about the two basic categories:

- Protective clothing is meant to keep dangerous materials from coming into contact with skin, eyes, and other parts of the body. Some items — rubber boots and aprons, for example — are totally impermeable and let nothing get through to the body surface. Other articles — your ordinary work clothes, for instance — let the air get through but keep out much of the dust and soil.
- Respiratory protective devices are breathing machines. Some devices are meant to supply you with air through a mask and hose where there is none to breathe in your work area or where the air is too dirty to breathe. Others are designed to filter out contaminants by various methods.

Fuel, oxygen, and heat must be present at the same time for a fire to occur.

Effect of Temperature on Limits of Flammability of a Combustible Vapor in Air.

## BASIC CONCEPTS

Most fires are the result of a chemical reaction between a fuel and the oxygen in the air. Materials such as methane, wood, coal, oil, grease, rags, and many plastics will burn when ignited in the presence of air. In each case, three ingredients are needed for an ordinary fire to occur: fuel, oxygen, and heat.

### The Fire Triangle

These three ingredients (fuel, oxygen, heat) must be present at the same time for the fire to occur. If any one is removed, the fire will go out; more important, if one is missing, the fire will not start. A triangle can be used to illustrate this basic principle. Each side of a triangle is given one of the labels: fuel, oxygen (or air), or heat. If any one is removed the fire goes out.

### Classes of Fires

For firefighting purposes, fires are now classified into four groups:

- Class A** those that involve ordinary combustible materials such as wood, coal, plastics, paper and cloth. They are best extinguished by cooling with water or by blanketing with certain dry chemicals.
- Class B** those that involve vapors above flammable or combustible liquids such as gasoline, diesel fuel, kerosene, and grease. They are best extinguished by excluding air or by special chemicals that affect the burning reactions.
- Class C** those that involve combustible materials in electrical equipment. They are extinguished by nonconducting extinguishing agents such as carbon dioxide and certain dry chemicals.
- Class D** those that involve combustible metals such as magnesium, titanium, zirconium, sodium, and potassium. They are extinguished by special extinguishing agents designed for such applications.

**Class A** Ordinary combustibles  
[wood; coal; paper]

**Class B** Flammable liquids  
[gasoline; diesel fuel;  
kerosene]

**Class C** Electrical

**Class D** Metals  
[magnesium; titanium]

Extinguishers are now labeled with special color-coded symbols (A, B, C, D) to indicate the class or classes of fires on which they can be used.

Class A - green triangle  
Class B - red square  
Class C - blue circle  
Class D - green star

# Toxic Gas Detector

## Matheson-Kitagawa Toxic Gas Detector

- Simple to use — easily operated by non-technical employees.
- Portable — lightweight, compact unit in a high impact plastic carrying case.
- Precise — the precision sampling pump is the key to accurate results using Kitagawa detector tubes.

An accurate and inexpensive method for determining the level of toxic vapors in lab or plant. Gives on-the-spot results to eliminate the need for expensive monitoring systems. Simply draw in a sample of the atmosphere through the detector tube and determine the concentration by comparing color changes within the tube. Detector comes in sturdy, high-impact carrying case with accessories and space for carrying detector tubes. Detector tubes are available for a variety of toxic vapors and come packaged in box for 10 tubes unless otherwise indicated. Pump is NIOSH Certified. Detector tubes are direct reading.

B1446 ..... 165.00

# Emergency Showers

## Emergency Showers

### Shower/Face Wash Assembly

This assembly mounts securely to floor with a 8" floor flange. On our 1373-2, the Face/Eye Wash (same as 1368) is mounted at waist height.

|         |  |        |
|---------|--|--------|
| B1373-2 | .....                                    | 425.00 |
| B1373-3 | Drench Shower without Face Wash Assembly | 235.00 |

\*Medical and industrial experience have shown that the optimal first aid prior to medical treatment for chemical splash consists of a 15 minute flushing of the injured part of the body with water with clothing removed. Safety showers must be within 10 seconds or 100 foot travel distance of a hazardous area (newly developed ANSI standard Z358.1). Where extremely hazardous conditions exist, showers should be located 10-20 feet from the source of hazard. Consult a physician for recommendation.

# Sample Procedure For Entry Into Confined Spaces

## I. Definition

A confined space is any relatively small enclosed or restricted space without proper life supporting atmosphere or in which mobility is restricted, such as, but not limited to; a bin, furnace, cupola, tank, pressure vessel, vault, well, boiler, or small compartment of a ship.

## II. Training

All employees required to enter into confined or enclosed spaces shall be instructed as to the nature of the hazards involved, the necessary precautions to be taken, including prior testing and purging if needed, the use of required protective and emergency equipment, and proper procedures for entering and working in such areas.

## III. Lockout

Prior to any employee entering any confined space, controls to equipment supplying or operating the device to be entered, or any device contained in the space, shall be locked out, valves to supply pipes serving the device or any device within the space shall be locked out or blanked, and any sewer or drain lines serving the space shall be blanked.

## IV. Testing

Before an employee is permitted to enter a confined space, the air in the space shall be tested with an approved device to determine if there is a deficiency of oxygen, the presence of toxic gas or vapor in excess of maximum allowable limits prescribed by the Department of Public Health, or an explosive atmosphere.

## V. Precautions

A. An employee shall not enter a confined space having an explosive atmosphere unless involved in correcting a condition which caused the explosive atmosphere and the condition cannot be corrected by any other means and the atmosphere cannot be purged below the explosive limit. All sources of ignition shall be prohibited in or around the space.

- B. If the atmosphere in the space is found to be either oxygen deficient or toxic, either ventilation shall be provided in a quantity that eliminates the hazard or respiratory equipment prescribed by the Department of Public Health shall be worn.
- C. A lifeline and safety harness shall be worn by an employee entering a confined space. These shall be so attached that the employee's body cannot be jammed in a small exit opening.
- D. Another employee trained in rescue procedures and equipped with the means necessary to effect a rescue shall be stationed outside the confined space in a position to watch the employee inside the space.
- E. If rescue efforts would involve lifting the employee vertically to remove him from the space, then a second employee must be in the immediate vicinity to assist the employee stationed at the entrance to the space, or a mechanical means to lift the employee out of the confined space shall be provided before work starts.
- F. Confined space entry procedures should be posted at the entry of each confined space or other appropriate locations subject to entry by employees.

---

*For MIOSHA safety standards covering confined spaces refer to construction standard Part 1, Rule 112, General Industry Standard Part 1, Rule 16 and Health Standard Rules 3301 and 6402.*

## **CONFINED SPACE (kən-fīn'ed, spās) N.**

"Confined space" means a space having a limited means of egress, which is subject to the accumulation of toxic or flammable contaminants or has an oxygen deficient atmosphere. Confined or enclosed spaces include, but are not limited to, storage tanks; process vessels, bins, boilers, ventilation or exhaust ducts, sewers, underground utility vaults, tunnels, pipelines, and open top spaces more than 4 feet in depth, such as pits, tubs, vaults, and vessels.

H-1c Training Director 40CFR 264.16 (a) (2)

The Ford Motor Company Training Program has been provided to date by the Facility Training Director, Mr. David S. Miller. Mr. Miller received his B.S. degree in geology from the University of Michigan in 1977 and has been involved with hazardous waste management since the effective date of the RCRA regulations. His experience in this field is as follows:

1980 - 1981 Environmental Coordinator for three hazardous waste treatment facilities. Developed facility operational, recordkeeping, and training procedures in compliance with RCRA and Michigan PA 64.

1981 - 1984 Environmental Coordinator for the APCM landfill. Developed operational, recordkeeping, and training procedures in compliance with RCRA and Michigan PA 64.

H-1 d Relevance of Training to Job Position 40CFR 264.16 (a) (2)

The job descriptions and job training program indicate that the training provided is relevant to the job position.

H-1 e Training for Emergency Response 40CFR 264.16 (a) (3)

Emergency response training is provided as shown in section H1-b.

H-2     Implementation of Training Program     40CFR 264.16 (b)

Documentation of the training provided is included in the facility notebook.

Examples of such documentation are as Attachment 22.

DOCUMENT OF HAZARDOUS WASTE TRAININGANNUAL REVIEW

Training Session Date: 10-05-83

Place: Job Site

Trainee: Murray D. Walker  
Ford Motor Company Employee

Previous Experience: Twenty-one years of experience as landfill bulldozer operator. Previously handled all wastes at the landfill prior to Act 64.

Aspects of Training: Waste characteristics and their physical properties were discussed in detail. General inspection items and procedures including waste verification were discussed. Pertinent waste handling and disposal regulations, particularly the management of run-off and run-on were addressed. Spill and Accident Prevention Plan, Contingency Plan and Emergency Procedures were discussed along with safety procedures and procedures for using, inspecting, repairing and replacing emergency and safety equipment. Fill and grading procedures for the site were studied.

Training Director: David S. Miller - Rouge Steel Company
